WOODWARD, J. H., 228, 253.

INDEX.

The asterisk (*) refers to duplicated pages in issue of November 1st.

Abdominal; section for pyosalpynx, 204; cavity, dangerous results of, 701.
Abnormality of diaphragm, 137.
Abortion; cleansing the uterus after, 220: suspected, 710.
Abscess; mammary, 32; cavities, drainage of, 71; pulmonary, 343; pleuritic, 373; of brain, 414; scrotal, 676; subscapular, case of, 687.
Abscesses; cold treatment of, 488; micrococci in, 590.
Absorption, power of, 563.
Abuse of medicines, 238.
Accident, an unusual, 111.
Accidental cure of stricture, 641.
Ache-tooth, cinnamon-bark for, 80.
Achillea millefolium in, 44.
Acid; carbolic, 43; injection for piles, 78; plea for, 309; hydrobromic, 123; sclerotinic, in epilepsy, 163; hyperosmic, in neuralgia, 247; hyponitrous, remedy in cholera, 248; osmic, in epilepsy, 276; hydriodic, in, 295; salicylic, on respiration, influence of, 485*; formic, a germicide, 533; hydrofluoric in, 598; phenic in, 664.
Acne; in fibre-dressers, 155; rosacea, treatment of, 332.
Acute; alcoholism, diagnosis of, 184; traumatic malignancy, 242; inflammation, 268; laryngeal catarrh, 301; traumatic malignancy, 321; urticaria, treatment of, 361; infectious diseases, treatment of, 378; pneumonia, 407; vomiting, 484; disease, diagnosis in, 603; painful paraplegia, 694; Bright's disease, 711.
Adenoma; of liver, 79; cystic-papillary, of neck, 678.
Adipose diarrhœa, 745.
Adonis vernalis and caffein, 412.
Adulteration; detection of, 194; of food, 617.
Affection, peculiar, of finger-tips, 693.
Affections, malignant, 524.
Albumen, tests for, 219, 587.
Albuminuria; hepatic, 332; causes, pathology, and treatment of, 353; in urine, 383; of pregnancy, cause of, 442.
Alcohol, 691; destructive effects of, 337; as medicine, 669.
Alcoholic; paralysis, 379; beverages, physical, 582; paralysis, pathology of, 662; injections in, 663.
Alcoholism; pathology of, 50; acute, diagnosis of, 184; in, 356; phosphates in, 472.
Algid collapse, 247.
Alimentation, rectal feeding and, 301.
Alkalinity of stomach, 80.
Alkaloids, micro-organisms and, 602.
Alopecia, 361; areata, case of, 250.
Alvelos, new cure for cancer, 43.
Amaurosis, uræmic, 222.
Amblyopia, tobacco. 136.
American medical colleges, 327.
Ammonia; picrate, in, 53; a prophylactic against cholera, 222.
Ammonium; bromide of, 22; bromide, in treatment of, 361.
Amputation; Syme's, modification of, 22; arrest of primary hemorrhage after, 329; of penis, 442.
Amyl; capsules, nitrite, substitute for, 51; nitrite of, 190, 725.
Anæmia; pernicious, 236; cerebral, or, 426.
Anæmic diseases, pathology of, 652.
Anæsthesia; local, by, 590; chloroform, 599.
Anæsthetic, 110; new local, 525, 528, 579.
Anal fissure treated without operation, 488.
Anatomy, metrical, 283.
Anchylosis of knee, 676.
Aneurism; ligate an artery for, 83; of left ventricle, 236.
Aneurisms, remarks on, 459.
Angina, diphtheritic, treatment of, 565; diet in, 734.
Animals; painless death for, 190; lower, cholera in, 471; diseases of, 539.
Anodyne, resorcin an, 192.
Anosmia, temporary, 250.
Anthracis bacillus, 493.
Anthrax, 160.
Antidote in strychnia poisoning, 725.
Antimony in clothing, 27.
Antipyretic; new, method, 191; treatment of, 378; treatment of wounds, 416; new, 560; decoctum limoni an, 568; lemon juice as, 600.
Antipyrin, 129, 244; its exanthem, 658.
Antiseptic; precautions, 221; Lister's treatment, 348; treatment of, 378, 406; dressings, how to prepare, 461; inhalations, 472; life, the great, 479; method, application of, 565; new, 663.
Antiseptics, use of, 324.
Anti-vaccination experience, 306.
Antrum, mucoid or puruloid engorgement of, 424.
Anus; dilatation for fissure of, 51; dangers of operations about, 709.
Aperients in scarlatina, use of, 333.
Aphasia complicated with chorea, 485; pathology of sensory, 741.
Aphonia, hysterical, seat of, 102.
Appendix, vermiform, perforation of, 456.
Apoplexy, 201, 234.

Arabum, elephantiasis, 334.
Areata, alopecia, case of, 250.
Arm, fractures of, 547.
Armamentarium, our, 169.
Arsenic; in gastric ulcer, 133; treatment of phthisis with, 629.
Artery; for aneurism, what caused Hunter to ligate, 83; main, ligature of, 726.
Arteries; torsion of, 357; syphilitic, curability of, 728.
Arthritis, rheumatoid, 273.
Ascites, idiopathic, 161.
Asiatic cholera, 297; prevention of, 573, 609.
Assemblies, public, panics in, 666.
Astragalus, excision, 238.
Asylums, lunatic, commitments to, 243.
Atresia vaginæ, with retention of menses, 650.
Atropine, salicylate of, 472.
Atrophy; idiopathic, of skin, 331; unilateral, 692; of optic nerves, 725.
Authority, dictum of, 81.
Avena sativa, 635.
Axilla, retention of hair in, 216.

Bacilli; tubercle in, 105, 331; Koch's staining of, 210.
Bacillus; anthracis, 493; typhoid fever, 493; of tubercle, 494; of malignant œdema, 494; of tuberculosis, 591.
Bacteria; in intestines, 329; affecting milk, 539.
Bacterial urethritis, 250.
Bandage, sodium, silicate of, 619.
Baths; cold, treatment by, 440; of mud, 652.
Bee-sting, peculiar results of, 633.
Beef, our supply, 421.
Beetles in stomach, 746.
Berlin polyclinic, 83.
Biology, new school of, 722.
Bismuth, subnitrate of, 22.
Black tongue, 19.
Bladder; male, papilloma of, 50; stone in, 98; inverted, 291; primary cancer of, 304; irritable, 709; lead-pencil from, 729.
Bleed a pregnant woman, when to, 485.
Blennorrhagia, acute, 108.
Blindness; temporary, 250; due to, 632.
Blood; poisoning 600; corpuscles, researches on, 652.
Body; impeachment of, 257; temperature, evening rise of, 480.
Bodies, dehydration of, 696.
Boils, more about, 417.
Bone; lesions, muscular paralysis with, 121; denuded of, 334.
Bones, cranial, of fœtus, 435.
Blood corpuscles; by malaria, changes in, 447; examination of, 603.
Boils, 277.
Borate of quinine, 158, 306.
Bottle in rectum, 358.
Bouton de gafsa, 556.
Bovine tuberculosis, transmissibility of, 248.
Brain; drainage of abscess cavities in, 71; tumor of, 119; epilepsy in, 162; abscess of, 414; concussion, defective vision from, 568.
Breast, sarcoma of, 519.
Breathing, hysterical or nervous, 159.
Bright's disease, 103; treatment of, 433; dyspnœa in, 486, 599; acute, 711.
Bromate, potassium, 727.
Bromide; of ammonium, 22; of sodium, 600.
Bronchial gangrene, 218.
Bronchitis treated, 406.
Bronchus, left, coal in, 634.
Broncho-pneumonia, pathology of, 637, 647.
Bronchocele, hydrofluoric acid in, 598.
Bulbar; excito-motor epilepsy, 425; epilepsy, differences between, 427.
Bullets, localizing, 183.
Burns, treatment of, 359, 598.

Cæcum, excision of, 664.
Cæsarian operation after Porro, 633.
Caffein; in diseases of heart, 130; and adonis vernalis, 412.
Calabash, tree fruit, 470.
Calculi, multiple, 137.
Calculus; 249, 335; vesical, removal of, 599.
Calomel; in diphtheria, 106, 728; in croup, 106; in chronic ulcer, 634.
Canary, scarlet fever in, 469.
Cancer; alvelos, new cure for, 43; epithelial, treatment of, 52; primary, of bladder, 304; hæmaturia in, 330; etiology of 333; of stomach, diagnosis of, 477; cauliflower, of uterus, 517; or gastric ulcer, 538; of male urethra, 631.
Cannibalism, 326.
Canned goods; alleged poisonous character of, 382; dangers in, 570.
Capsular, intra, fracture, 472.
Carbolic acid; death from, 52; injections of, 78, 128, 664; treatment, 217; plea for, 309; large doses of, 413.
Carcinoma; of cervix uteri, 260; of larynx, 290.
Cardiac disease, insanity and, 52.
Caries, dental, in Normandy, 307.
Case of homicide, 330; elephantiasis arabum, 334; poisoning from, 469*; hermaphroditism, 516; gastric ulcer, 538; fruhjahr-catarrh, 546, 554; extra-peritoneal rupture, 557; ovariotomy, 701; headache, 729.
Castration of women, 159.
Catarrh; acute laryngeal, 301; fruhjahr, case of, 546, 554; diarrhœa or intestinal, 719.
Catarrhal ophthalmia, 576.
Catheters and self-catheterism, 220.
Catheterism, self, and catheters, 220.
Cattle, typhoid fever from, 698.
Cauliflower; cancer of uterus, 517; excrescence of, 554.
Causation of labor, 688.
Causes of death, 351; pathology, and treatment of albuminuria, 353.
Caustic-holders, improvement in, 418.
Cautery, actual, 126.
Cavities, pulmonary, operative opening of, 413.
Centenarians, reputed, 381.
Century, worth living, 484.
Cerebral; physiology, 13; anæmia, 426; circulation, influence of,
Cerebro-spinal meningitis, 232.
Cervical, upper, spina bifida in, 53.
Cervix; lacerated, 222; uteri, laceration of, 554.
Chancre of tonsil, 78.
Chemistry of wines, 185.
Chicken cholera, bacillus of, 539.
Child, female, lithotomy in, 487.
Children; comedones in, 11; diarrhœa in, 14,

Water; cure in diphtheria, 107; supply, 195.
Weak ankle, treatment of, 383.
Weight, unusual, of fœtus at, 131.
White clover, 492.
Whooping-cough; picrate of ammonia in, 53; treatment of, 477.
Wind-pipe, cockle-burr in, 478.
Wines, chemistry of, 185.
Winter hæmoglobinuria, 621.
Women; castration of, 359; veratria in pruritus of, 191; pregnant, when to bleed, 485; internes in Paris hospitals, 603.
Worm, tape, treatment for, 471.
Wound, gun-shot, 302; of vulva, homicide by, 330.
Wounds; union of, 359: in children, antipyretic treatment of, 416; pistol-shot, 476*; micrococci in relation to, 590: treatment of, 660.
Wry-neck, non spasmodic treatment of, 72.

Yellow fever, hot-beds of, 19.
Youth, alcoholism in childhood and, 356.

437; symptoms in diseases of, 46; ephemeral high fevers in, 162; summer diseases of, 404; antipyretic treatment of wounds in, 416; throat, instrument for penciling, 488; respitory tract in, 565; dose of potassium iodide for, 567; pleasant quinine mixture for, 633.
Childb[illegible] alcoholism in, 356.
Chloro[illegible]m; not a tænifuge, 53; syncope treated by reversing, 77; for tape worm, 471; anæsthesia, 599.
Cholecystotomy, 153, 624.
Cholera, 49; infantum, 132, 350; treatment of, 163, 183, 193, 261, 322, 333, 358, 473*, 568; by rail, transmission of, 166; British commission, 195: ipecacuanha in treatment of, 211; ammonia a prophylactic against, 222; Berlin physicians and, 223; hyponitrous acid, remedy in, 248; French theories on, 281; Asiatic, 297; prevention of, 573, 609; theories of, 406; knowledge of, imperfect, 428; in Toulon, treatment of, 465; in lower animals, 471; and syphilis, 488; microbe of, 492; bacillus, 494; at Paris, 562; German precautions, 626; Ricord, on contagion of, 665; guarding against, 731.
Choleraic alvine discharges, poisons in, 72.
Chloride, ferric, 23.
Chorea? is fright an essential pathogenic element in, 225; as a complication of pleurisy, 246; aphasia complicated with, 485.
Choroidal disease, relations to, 113, 145, 150.
Chronic; mercurial poisoning, 22; blennorrhagia, 108: inversion of uterus, 175; nephritis, case of, 358; urticaria, treatment of, 361; secondary glaucoma, 470*; diseases, treatment of, 509, 541; indigestion, treatment of, 702.
Cigarette smoking, 727.
Cinnamon bark, 80.
Clavicle, fracture of, 206.
Cleansing the uterus after abortion, 220.
Clinical; phenomena following, 93; observation, 270.
Clitoris, extirpation of, 107.
Clothing, antimony in, 27.
Coal in left bronchus, 634.
Cobra bite, recovery, 111.
Cocaine; hydrochlorate, 525, 590; muriate of, 526, 528, 530, 579, 693, 727, 728.
Cockle-burr in windpipe, 470.
Codeia jelly and glycerine, 20.
Coitus, preventing, 475.
Cold; ablutions of feet for, 249; treatment of neuralgia, 358; baths, treatment of puerperal fever by, 440; abscesses, treatment of, 488*; water in, 545.
Colic, uterine, 160.
Collapse, algid, 247.
Colleges, American medical, 327.
Color, perception, theories of, 331.
Coloring, new method, 79.
Colotomy, 629; inguinal, 105.
Comedones in children, 11.
Commitments to lunatic asylums, 243.
Communicability of phthisis, 357.
Compensatory hypertrophy, 211.
Complication of pleurisy, chorea as, 246.
Compound fractures, treatment of, 228, 253.
Conception; without intromission, 23; prevention of, 305.
Concretions in the pancreas, 742.
Concussion, brain, from, 568.
Condy's fluid, suppressed lochia treated by, 417.
Condyle, external, fracture of, 677.
Congenital hernia, radical cure, 79.
Conia in epilepsy, hydrobromate of, 136.
Conjunctivitis in new-born, 77.
Constipation, 189.
Consumption, versus tuberculosis, 18; promises to cure, 635; communicability of, 727.
Consumptives, resort for, 308.
Contagion of cholera, 665.
Contagiousness of diphtheria, 413.
Contra-indications in medicines, 20.
Contraction, Dupuytren's, of fingers, 69.
Contributions of physicians, 3.
Convulsif Tic, cured, 333; convulsions, 416.
Copper, sulphate, large doses of, 189.
Copulation, male, without emission, injure? 479.
Cord? tie the, 359; umbilical, elastic ligature for, 515.
Cornea, treatment in deep ulcers of, 465.*
Corneal disease, 85.
Corpuscles, blood, by malaria, changes in, 447.
Corrosive sublimate a, 595; injections of, 52; how to prepare, 80.
Cortical and bulbar epilepsy, differences between, 427.
Cortico-cerebral epilepsy, 427.
Cough; elenine for, 136; remarkable case, 463; whooping, treatment of, 477.
Coryza, treatment of, 43.
Coxalgia, double, with, 677.
Cranial bones of fœtus removed from rectum, 435.
Cranio-tabes, phosphorus in, 246.
Cremation, 731; legal views about, 16; progress of, 412.
Crematorium, the Lancaster, 723, 731.
Crematory, ancient, 111.
Crooked noses, cure of, 467*.
Crossing the legs, 303.
Croton oil for tape-worm, 471.
Croup; tracheotomy in, 94, 605, 613; treatment of, 565; calomel in, 106; membranous, 285; treatment of, 62; diphtheritic, 290; tracheotomy in, 180.
Crushed ice, use of, 359.
Culture, physical, in, 724.
Curability of syphilitic arteritis, 728.
Curious diet in Texas, 173.
Cutaneous therapeutics, 402.
Cutting the horns of cattle, 476.
Cyst; ovarian-monolocular, 9; dermoid, 550; dangerous results of, 701.

Intromission, conception without, 23.
Inversion, chronic, of uterus, 175.
Inverted bladder, 291.
Investigation of disease, 355.
Iodide; potassium, 131, 135; for children, 567; glycerized, in small-pox, 192.

Iodoform ; solution, for injection, 108 ; efficacy of, 160 ; diphtheria treated by, 218.
Injections ; of, 488 ; in treatment of gout, 567 ; in organic disease of, 694.
Ipecacuanha in cholera, 211.
Iridin in vomiting of pregnancy, 53.
Irritable ; bladder, 709 ; eyes, 741.
Irritative diarrhœa, formulæ for, 163.
Iritis ; recurrent, 113, 145, 150 ; serous, 470*.
Iron ; subcutaneous injections of, 76 ; alum in, 471.
Ixodes, the, 486.

Jackass, who was ? 698.
Jaundice, significance of in diagnosis, 64.
Jequirity, 79, 613.
Joint ; disease of, 126 ; muscular wasting in, 349.
Joints, inflammation of. 50.
Juvenile earth-eater, 659.

Kairin, physiological effects of, 294.
Kefir, 99.
Kidney ; fixation of movable, 125 ; hæmaturia in cancer of, 330 ; ruptured, treatment of, 532 ; disease, caused by, 630.
Kidneys, tubercle bacilli in, 331.
King of Italy's cholera tour, 731.
Knee, anchylosis of, 676.
Knees, both, strumous inflammation of, 677.

Label poisonous prescriptions, 187.
Labor ; digital dilatation during, 39 ; management of, 407 ; obstructing, peculiar-shaped placenta, 486 ; cold water in, 545 ; causation of, 688.
Laboratory, Pasteur's, 362.
Laceration of cervix uteri, 554.
Lacerated cervix, 222.
Lancet, use of, 54.
Laparotomy ; for volvulus, 137 ; successful, 302.
Large doses of quinine in, 692.
Larvæ of œstrus bovis in, 164.
Laryngeal ; catarrh, acute, 301 ; growths, removal of, 568 ; intra, operations, cocaine in, 728.
Laryngo-tracheotomy after, 81.
Larynx, syphilitic ulcer of, 51.
Lawn-tennis, leg, treatment of, 597.
Laws governing the removal of the dead, 593.
Lead ; poisoning, blindness due to, 632 ; pencil removed from bladder, 694, 729.
Leg, dressing for ulcers of, 597.
Legs, crossing the, 303.
Legal ; views about cremation, 16 ; evidences of, 419.
Leiomyoma, cystic uteri, 40.
Lemon-juice ; in malaria, 415 ; as antipyretic, 600.
Lepers on exhibition, 167.
Lesions of snake venom, 376.
Lethargy, protracted, 600.
Leucorrhœa, achillea millefolium in, 44.
Life, the great antiseptic, 479.
Ligation of external piles, cause of death after, 438.
Ligature ; elastic, 133 ; for, 515, 635 ; of main artery, 726.
Lightning strokes in France, 139.
Limb, inflammation of, 726.
Limitation of families, 193.
Lingual nerve, stretching of, 726.

TREATMENT OF SIMPLE ULCER OF THE STOMACH.

Memoir read before the Soc. Médicale des Hôpitaux, of Paris.

BY PROF. DEBOVE.

The long-recognized and classic treatment of simple ulcer of the stomach consists in submitting the patient to an exclusive milk diet, accompanied by the administration of alkalies, represented by Vichy water, lime water, etc.

This treatment has proven successful in many cases, but frequently fails, or, though well supported in the beginning, induces later on dilatation of the stomach and its attendant evils. [On account of these accidents, Prof. Bouchard has instituted what he calls the "dry diet." The food is taken in small quantities at a time, and very little liquid is allowed.]

In order that an individual may be properly nourished on an exclusively milk diet, the ingestion of large quantities—about four quarts a day—is necessary, and even more is required if the patient leaves his room and leads a more active existence. If the attempt be made at the same time to administer any notable quantity of Vichy or lime water, dilatation of the stomach is inevitable, and this complication alone may cause death.

To obviate these accidents, I formerly proposed the use of a smaller quantity of milk, rendered more nutritive by the addition of milk powder or condensed milk. But when I wished to carry this idea into practice I met with many difficulties, due to the inferior quality of the condensed milk and milk powders as commonly found in commerce. And even under the very best conditions, many patients were not able to long continue this diet. I have also prescribed the concentrated powders of meat; but, notwithstanding their usual facile digestibility, they were always badly tolerated, inducing gastralgic pain, vomiting, and even hæmatemesis.

It may then be said, that most forms of diet, vaunted in the treatment of simple ulcer of the stomach, fail very frequently, and in certain cases also induce grave accidents.

The ideal treatment in such a case would be to suspend completely for a time the functions of the stomach; for the action of the gastric juice, if not the primary cause of the ulceration, at least contributes to its continuance. But it is not possible to keep such patients fasting any great length of time, and alimentation by peptonized enemata has failed. Under such circumstances, we have been led to institute a form of treatment, having its basis entirely in theory, but which has given the best practical results in extremely grave cases.

The gastric juice has an acid reaction, and this acidity is absolutely necessary for the exercise of its digestive action, as well in vitro, as in the stomach. "This acid reaction," writes Claude Bernard, "is so characteristic of the gastric juice, that it suffices to change the reaction to deprive it of its physiological properties; so that it might in reality be said that an alkaline gastric juice is no longer, properly speaking, gastric juice. Whence it results, that if an alkaline reaction is kept up during the sojourn of the aliments in the stomach,

they would not be digested, the gastric juice would have no action on them; but on the other hand, it would not act either on the ulcer, if such exists, and the aliments would pass undigested into the intestine, with an alkaline reaction, that is to say, under the most favorable conditions for intestinal digestion; this digestion alone would furnish sufficient material for the reparation of the tissues."

We have instituted several experiments to determine whether this mode of reasoning was simply a matter of theory. We have, on several occasions, introduced into the stomach a melange formed, for instance, of twenty grammes of meat powder (representing more than eighty grammes of meat) and ten grammes of bicarbonate of soda.

After the space of one hour, on washing out the stomach (lavage), no trace of the meat was found in the liquids obtained, and these liquids were neutral in reaction. If this lavage of the stomach was performed after a quarter, a half, or three-quarters of an hour, the liquids obtained contained a variable proportion of the meat, but no trace of peptones was found, and the reaction was always neutral. The bicarbonate of soda sufficed then to keep up a neutral condition of the contents of the stomach, while the absence of peptones demonstrated the non-digestion of the meat, and the probability that it passed undigested into the intestine.

In four very grave cases of ulcer of the stomach, two having been already treated for a considerable period by the milk diet, with Vichy water, we obtained an immediate cessation of the pain and vomiting, and after two months the condition of the patients was so favorable as to warrant a hope of speedy cure. I will describe in detail the exact course pursued in these cases. During the first few days we washed out the stomach in order to free it from the more or less acid contents, and we do not consider this proceeding at all dangerous. We have not observed that such lavage had any tendency to induce hæmatemesis; and if the stomach-tube used is sufficiently soft, while proper precaution be exercised there is no danger of causing perforation, even if the tube should touch the ulcer itself.

This preliminary lavage of the stomach is not indispensable if there is no dilatation of the stomach, and we generally discontinue it after a few days.

Three meals daily were allowed, and consisted of 25 grammes of concentrated powder of meat given in milk or water, with the addition of 10 grammes of bicarbonate of soda. During the day the patients were allowed to drink a quart of milk with lime water or saccharate of lime. This melange was ordinarily administered through the stomach-tube, for the patients, accustomed to the introduction of the tube, preferred taking it that way on account of the disagreeable taste of the mixture of meat powder and so large a proportion of bicarbonate of soda. But, if desired, the bicarbonate can be administered alone in wafers, five grammes immediately before taking the meat powder, and the remaining five grammes a quarter of an hour later.

Ten grammes of bicarbonate of soda at each repast may seem a very considerable dose, as thirty grammes, or one ounce, is thus taken in the twenty-four hours, and the accidents due to the so-called alkaline cachexia might be dreaded. For my part, I have never observed any accident induced by this treatment, even after it has been continued for months.

Physicians also who have administered alkalies in very large doses in the treatment of rheumatism, have never observed any accidents. Prof. Jaccoud has administered twenty grammes per diem.

"We have not observed," he writes, "in any of these patients, any of the symptoms which have been attributed to the alkaline cachexia."

Prof. Charcot uses almost identical terms. "Notwithstanding the long-continued administration of alkalies, principally bicarbonate of soda, in very large doses (thirty or forty grammes per diem), we have never observed any pathological results of sufficient gravity to cause inquietude."

Although, as we have said, we never have had any accidents from the administration of these doses it may be well to commence with a smaller dose which may be rapidly increased if the stomach is found to tolerate the alkali.

Bicarbonate of soda has the advantage of not having any irritant action on the mucous membrane lining the stomach, but by decomposition in the presence of the acids contained in this organ it gives rise to the development of carbonic acid, which causes eructation, and at the temperature of the stomach may contribute to produce dilatation. It is also very soluble and easily absorbed, whence, if the aliments remain any length of time in the stomach, it may be absorbed before they have entirely passed into the intestine. On account of these properties we have essayed to replace it by other antacid substances, such as lime, saccharate of lime, carbonate of lime, medicinal soap, and magnesia.

Lime was employed in the form of lime water;

but, as this liquid contains but a little over one gramme of lime per litre, the large amount of liquid required might give rise to dilatation of the stomach. Again lime has, if given in very large doses, an irritant effect on the stomach. Saccharate of lime has a less disagreeable taste, is more soluble, and is less irritating, than other preparations of lime. We have employed it dissolved directly in milk.

Precipitated carbonate of lime has no irritant action on the stomach, but gives rise to a considerable development of carbonic acid gas in saturating the acid contents of the organ.

Medicinal soap has a somewhat irritant action on the stomach if given in large doses. It should always be purified by dissolving in absolute alcohol before being used for this purpose. This soap, a stearate of soda, is decomposed on contact with the acids of the stomach, but the matters which result from this decomposition have no ill effect. Magnesia will also saturate the gastric acids, but cannot be employed in sufficient dose, on account of its purgative action.

The advantages and disadvantages of each one of these substances have led me to combine their use in the following manner.

The patient makes three repasts daily, composed each of 25 grammes of concentrated powder of meat in milk or water, to which is added the following powder:

R.	Calcined magnesia,	15 grains.
	Prepared chalk,	30 grains.
	Saccharate of lime,	15 grains.

M.

Immediately before each meal the patient takes a cachet containing two grammes of bicarbonate of soda, and a quarter of an hour after meals he again takes four grammes of the same soda salt.

The patient must not be allowed a great quantity of liquid. We allow a quart or a quart and one-half of milk per diem, containing from one to one and a half drachms of saccharate of lime.

This must be taken in small quantities at a time. Many observations have convinced us of the extreme value of this diet and treatment, carefully carried out, not only in simple ulcer but also in many other forms of non-ulcerative gastritis.

—A house-surgeon at St. Eugénie Hospital is believed by M. Verneuil to have become inoculated with tubercle during a post-mortem examination. The same accident, it will be remembered, occurred to Laennec, but he did not die till twenty years later.

COMMUNICATIONS.

CONTRIBUTIONS OF PHYSICIANS TO ENGLISH AND AMERICAN LITERATURE.

BY ROBERT C. KENNER, M. D.,
Of South Carrolton, Ky.

"But the knowledge of nature is only half the task of a poet; he must be acquainted likewise with all the mode of life. His character requires that he estimate the happiness and misery of every condition; observe the power of all the passions in all their combinations, and trace the changes of the human mind as they are modified by various institutions and accidental influences of climate or custom, from the sprightliness of infancy to the despondence of decrepitude." * * * * "His labor is not yet at an end; he must know many languages and many sciences."—*Samuel Johnson.*

The writer of prose or poetry who would produce works which contain thoughts and inferences which will go down to posterity, must of necessity be acquainted with the passions of men in all the grades of society. Mere scholarship can never make up this want; and the monk, versed in all the erudition of the ages, would come far short of producing poems which would touch the heart of a nation as do those of Robert Burns. Shakespeare was acquainted with the hopes and fears of all classes. He was really a man of all the people, and had mingled in their loves and hates, and known the slavery of poverty and the liberty of wealth, and he was the greatest interpreter of the human heart and mind that has ever given the resources of his study to the world. Blair properly defined poetry to be "the language of passion." Without an acquaintance with the doings of the low, the great, and the wise and the simple, it is not easy to imagine how a poet, a man of genius, can breathe into his productions the breath of passion. Of course, being learned, he could imitate; but the imitation would be transparent, and altogether lack the coloring of nature, which is obtained by contact with the world, and which makes the idealistic creature of the true poet a real personage. Those authors, then, who have left behind works which will always be read and cherished, have been children of nature and citizens of the actual world, have known how hardships affect the heart, and been participants in the struggle with opposition and disappointment for place and recognition in the world. When one reads the "Traveler," he feels with Goldsmith that love of

country which beams throughout the poem, and he enters with delight into those splendid meditations upon the countries through which he roamed as a wandering musician. Goldsmith knew the common ambitions, passions, and aims of the people in all these countries, and easily turned this treasured knowledge into immortal verse.

Now the physician, more than any other man in society, occupies the position to observe the ways and passions of all. He is called when death is about to remove the loved one from the family circle—is almost daily called to witness the most vivid depictures of the passions. He goes to the palaces of the rich, and to the poor man's hovel, and to the den of wickedness, where he often has to remain long, and of course is compelled to learn more or less of their actions, superstitions, and modes of life. To him the matron and the maid, and the saint and the sinner, open their hearts, and nothing is withheld. He is then eminently in the place to observe all those qualities of heart and mind which form such a large part of the poets' essential knowledge.

In an original article of any reasonable length, I can only give a slight notice of a few of the many to whom a place would be given in anything like a treatise on this subject.

I shall not go back much beyond the Elizabethan period. Beyond that time the medical science had not begun the great strides which characterizes its march after Harvey's discovery. This brilliant period of intellectual vigor, like every subsequent one, has witnessed a number of physicians who have found rest and mental recreation in their contributions to literature.

A little prior to Elizabeth's reign, Thomas Linacre (1460–1524) flourished. He was physician to Henry VII., and one of the most eminent medical men of his day. He taught Greek and medicine at Oxford, and was a great philologist and linguist. His fame as a man of letters was established by his numerous translations of literary and professional works, and by the publication of his own treatises, which embrace several subjects. He was the first president and founder of the Royal College of Physicians.

Prominent among that brilliant galaxy of luminaries of Elizabeth's time stands Dr. Arthur Johnston (1587–1654). After taking his medical degree at Padua, he was chosen physician to Charles I., and besides attaining eminence in his profession, wrote many poems and psalms which have been praised for their elegance and general poetical merit.

In this connection John Cains (1510–1573) deserves mention. He was a great friend of education, and the founder of Cains College. He was a great physician, having written several medical works, and been the much-loved physician of Edward VI. He wrote several works on natural history, and a "History of Cambridge."

Dr. John Arbuthnot (1667–1735) was declared by Swift and his contemporaries generally, to have been the most intellectual and humane man in the world. He was the intimate friend of Pope and Swift, and engaged with them in several literary enterprises. He was the chief contributor to "Martinus Scriblerus" and "History of John Bull." He displayed his talents in other works which may be called fragmentary, and among them may be classed his poems. His "Know Thyself" is esteemed by the best judges to be the most philosophical poem in the English language. He was a member of the Royal Society, Fellow of Royal College of Physicians, and Physician to Queen Anne. He attained the greatest eminence in his profession, and was the greatest example of his times of a union of the literary man and physician. His medical productions exhibit the greatest profundity of research and observation. Shaw says, "He seems to have fully deserved the admiration lavished upon him by all his friends, as an accomplished scholar, an able and benevolent physician, and a wit of singular brilliancy and fertility."

Sir Thomas Browne (1605–1682) a man of wonderful erudition and boundless benevolence, practiced medicine at Norwich nearly all his life. He is regarded as one of the greatest and most representative men of his day by all authorities on English literature. His writings cover a considerable field of inquiry. His "Religio Medici" and "Treatise on Vulgar Errors" are two of his works which will give the reader the best idea of his genius and scholarship.

Sir Samuel Garth (——1718), one of the most notable men of his age, was physician to George I., and Physician-General to the army. His "Dispensary," a poem of great felicity of versification, teeming with pathos at once and satire and ridicule, has secured him an imperishable name in the annals of literary history.

Henry Vaughan (1621–1695), "The Silurest," was a poet and miscellaneous writer of great merit, as well as an active and successful practitioner of physic. The chief objection offered to his poetry is that it has a Welsh harshness. But the lover of true passion, set forth in verse, will always read and admire the pure and lofty poems of Henry Vaughan.

Sir Richard Blackmore (1658–1729), enjoying a wide reputation and doing an extensive practice, found time to dally with the muses, and has left to posterity "The Creation," a poem the praise of which Dr. Johnson joined in giving, and which is admitted in the collection of British Poets.

The poems of Mark Akenside (1721–1770), after the publication of his "Pleasures of Imagination," took a place in the literature of his country it is safe to say they will retain. His poesy belongs certainly among the most ornate productions in the language. He enjoyed great popularity as a medical writer and physician. He was a painstaking investigator and student of medicine, and his numerous works show the depth of his research.

Dr. John Armstrong (1709–1779), for a time surgeon of the army, and constantly engaged in medical practice, rode his Pegasus even into the Esculapian domains, when he wrote the "Art of Preserving Health." His literary contributions are of sufficient merit to embalm his memory.

Benjamin S. Barton (1766–1815), a man of the broadest culture and most varied attainments, did an enormous practice in Philadelphia, and upon the death of the immortal Rush he was elected to the chair of Practice in the University of Pennsylvania. His claims on posterity rest chiefly on his "Elements of Zoology and Botany."

John Bell (17—1820), that great English master of surgery and anatomy, gained too prominent a place in the history of medicine of his time ever to perish. Besides his classical works on anatomy and surgery, he exhibited fine literary taste. His "Observation on Italy," is a work in the happiest vein of composition.

Probably no one deserves mention in this connection more than Nathaniel Cotton (1707–1788), that pure-minded and beloved alienist, to whom, as his medical attendant, the immortal author of "John Gilpin" and "The Task" was so much attached. His poems abound in pathos and the qualities of true poetry. His "Visions in Verse," and miscellaneous poems, are greatly admired.

A brief notice of George Crabbe (1754–1832), who was acquainted with the medical sciences, and practiced for some time in his native town, needs be made here. But after going to London and obtaining the friendship of Burke, he quitted his profession, and set out upon a literary life, and enjoyed great prosperity. His "Library," and other poems, attest his genius in a manner which will prevent it ever being called in question.

The name of James Currie (1756–1785) will always be prominent in British biography. He was one of the greatest medical practitioners and reformers of his particular day, having been first to call attention to the use of water in fevers. He contributed to literature, and his "Life of Robert Burns" is a masterpiece of biographical literature, and specifically a book which conveys the fairest and most liberal idea of that wonderful "babe of genius." More interest is felt in Currie, when we remember he was cut off from life at 29 years of age, and just as his genius was ripening and rejoicing.

Erasmus Darwin (1721–1781) was a poet of unquestionable genius. He made unhappy selections of subjects, yet his "Botanic Garden," and "Loves of the Plants" still find readers, and will hold their place as long as literature lives. He attained eminence in the medical profession, and loved it, and devoted some of his best time to its advancement.

His contemporary, Hugh Downman (1740–1809) was a popular physician, as well as a poet of a high order of genius. He wrote "Infancy," the merit of which cannot be denied.

That exulting genius, Oliver Goldsmith (1731–1774), studied medicine at Edinburgh and Leyden, at which latter place he took the degree of M. B. While he made literature his life-work, he alternated it with frequent returns to the Æsculapian science of his first love. His poetry is universally admired. He was a scientific man of no mean proportions, as may be seen from his "Animated Nature."

Lemuel Hopkins (1750——) was one of our foremost American practitioners, and one of our representative men. He was a member in high standing in many societies. He wrote considerable in prose and verse, and died having attained, beside a high reputation as a physician, an enduring fame as a poet and literary man. His poems are productions of great elegance and beauty.

John Keats (1796–1821), This meteoric genius had drunk from all the springs of medical learning. His short life, marred by ill-health, prevented him from engaging in the practice of his profession. He was about to engage as a ship surgeon before his last illness. Keats was a man of great genius, and his poems, as the late Dr. R, O. Cowling said, are "the most beautiful in the language."

Thomas Percival (1740–1804) was connected with the best interests of his profession and general literature as much as any man at the dawn of the nineteenth century. He wrote a work on

"Medical Ethics," and among his literary works his "Moral and Literary Dissertations" may be mentioned as best.

Besides being a great physician and surgeon in the Revolutionary War, Dr. David Ramsey (1749–1805) was one of the most active men in those stirring times in helping to establish and maintain the independence of the Colonies. He was a tireless and profound student and writer. His contributions to American literature were numerous, and occupy the highest rank of authorship. As an historian, he was singularly accurate, original, and charming. He made several translations, and wrote a "History of the United States," of "Revolutionary War," "Life of Washington," and many other works of a similar nature, which maintain the esteem which his countrymen do and have ever felt for him.

Tobias George Smollet (1721–1771), the immortal author of "Roderic Random" and "Peregrine Pickel," will always hold a first place among the English classical authors. He had devoted himself to study and practice of medicine for a period of his life, having been a ship surgeon and practiced in Jamaica.

No man has enjoyed a larger and sincerer share of popular and professional love than Dr. Benjamin Rush (1745–1813). He was professor of "Practice of Medicine" in the University of Pennsylvania, and left an impression on medical practice which lasted longer than that of any American teacher. He joined with his whole heart in the cause of his fellows in throwing off the British yoke, and was a member of Congress and a signer of the Declaration of Independence. He contributed largely to medical literature, and his "Treatise on the Human Voice," and smaller works, entitle him very justly to a place in this article.

A great, and in some respects a remarkable man was John Whitehead (—— 1804). He was a great Methodist revivalist, and an enlightened and lovable physician. He attended John Wesley in his last illness, and wrote his life in two volumes, in which he displayed great force as a biographer.

John George Zimmerman (1728–1795) enjoyed a world-wide reputation as a physician. Was physician to the court. He was called to attend Frederick the Great in his last sickness. He was a prolific medical writer, making a great impression on the medical mind of his day. His "Treatise on Solitude," which was one of the most popular works in the language, now has many admiring readers.

It is impossible, in the range of an original article of reasonable length, to mention, even in the slightest way, the many doctors who have contributed to literature from the time of Rush and Zimmerman down to the day of our own great American Arbuthnot, Oliver Wendell Holmes, and J. G. Holland, that great poet and literateur. I shall then go no further in what would be a pleasant task of dwelling on the qualities of men who were most fit, and did most to make our literature.

INTESTINAL OBSTRUCTION—RECOVERY.

BY HENRY D. FULTON, M. D.,
Of Pittsburgh, Pa.

The following case may possess some interest, on account of recovery from an intestinal obstruction which rendered the patient's condition for some time apparently hopeless.

Was called May 2, 1884, to see J. McC., æt. 30, swarthy, robust river-man, who stated that his bowels had not operated for a few days, and that he was suffering severe colicky pains. The patient could assign no cause for the trouble, was not ruptured, had been of rather constipated habit for some time, and was an habitual drinker of bad whiskey. The abdomen was but slightly swollen, and not painful on pressure. Being in great distress, he was at once given morph. sulph. gr. $\frac{1}{3}$ hypodermically, and a prescription containing hyd. chlor. mit., gr. x.; leptandrin, gr. j.; with a little bicarbonate of soda, to be given in two doses, was ordered. The patient was not seen until the next day, when his symptoms were greatly aggravated. His brother stated that he had given him a large dose of castor oil in the night, which together with the medicine of the day before, had not operated.

The pain had returned with increased severity, and the abdomen was more swollen than when first seen. The obstruction, upon physical exploration, could be determined. The pain was severest in the umbilical region, and was not increased by moderate pressure.

A strictly milk diet was directed, and the patient given another hypodermic of morphia. A large injection, containing turpentine, was administered, and directions given to the attendant to repeat it in three hours. Morphia sulph. gr. $\frac{1}{3}$, was given in solution every two hours, and the belly rubbed with a liniment composed of equal parts of olive oil and laudanum. On the third day his condition was unchanged, save a relief from pain. He expressed a desire for some solid food, but was restricted to the milk.

In the evening he had an attack of vomiting, in

which a large quantity of stercoraceous matter was thrown up. Copious soapsuds enemata were administered through a gum tube, which was passed several feet into the bowel, but without accomplishing anything, and the progress of the case in the next day or two was most unfavorable. The vomiting of fæcal matter recurred at intervals of a few hours, only a small amount at a time being ejected. There was as yet, however, no elevation of temperature, or other signs of approaching inflammation. The skin was cool, moist, and exhaled a disagreeable odor. The expression of patient's face, even when free from pain, was anxious and distressed. The pulse was feeble, and the strength markedly reduced.

The morphia was continued at longer intervals, and nothing else given except milk and an occasional drink of flaxseed tea. An effervescent injection (a seidlitz powder) was administered without effect.

On the ninth day enemata of warm olive oil were administered through the tube passed into the bowel, and after these had been repeated a number of times, a quantity of fæces came away with them. This was followed soon by several free passages, unprovoked by injections.

The colon was again thoroughly irrigated with soapsuds, and the case now assumed a favorable aspect. The stercoraceous vomiting entirely ceased, pain and tympanites disappeared, and the patient quickly improved to recovery. The result was gratifying, but what was the exact nature of the obstruction was not definitely known, nor its situation positively diagnosed.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. Seelye, A. M., M. D.

Hydrarthrosis.

This patient whom I now show you is a legacy received by us from the surgical side, and she is a woman who was attacked with rheumatism soon after confinement. There was nothing unusual about her confinement, and she made a good recovery, and not until the child was a week old did this trouble begin. It came on first with pain and swelling in the ankle-joint, and then after two months it attacked the left knee; and it has been confined to these two joints. But when it appeared in the knee it immediately subsided in the ankle. With the advance of the trouble in the knee you observe how swollen it has become, and the direction which the leg has taken in reference to the thigh. That is the position of greatest ease, with the leg drawn up and the thigh flexed, and it will become permanently fixed in this position unless the adhesions which have formed shall be broken up. She has what is called a hydrarthrosis, and the synovial cavity is distended with fluid. But the inflammation, besides involving the synovial cavity, also generalized about the joint. It is a panarthritis, so to speak. When she came over to this side she was without fever, but there was great tenderness and very great pain in the joint, and especially at night. The part was placed in a comfortable position, and then a Paquelin's cautery was applied, and these longitudinal lines, which you see passing over the joint, are the marks of the cauterization. They were made by drawing the cautery very gently over the skin. As a result the pain has subsided considerably, and there is no longer such great tenderness in the part. Her constitutional treatment consists simply in the administration of an effervescent tonic draught, containing iron, the sulphate of quinine, bicarbonate of potash, and lemon juice. Under this treatment there has already been a decided diminution in the size of the joint, and there is not so great tension as there was, and she can now bear considerable pressure, while before she would scarcely let you put your fingers upon the skin. I show her to you as an illustration of what sometimes happens in rheumatism, and especially if it is confined to one or two joints.

In ordinary cases of rheumatic fever recovery takes place without any ankylosis or deformity of the joint remaining. We unfortunately confound a number of distinct affections in the term rheumatism; and here we have a case which is entirely different in character from an acute inflammatory rheumatism. For we have an inflammation involving only these two joints, instead of several joints, and it is a disease which does not follow the course of the arthritic inflammation which occurs in cases of ordinary acute rheumatic fever, and it has no distinct acute termination. But it is a disease which terminates by leaving the joint, not as it was before, but with permanent swellings from the exudations, and it may be with still farther deformity from ankylosis.

I also show you this case to call your attention to a form of counter-irritation which is of very great value. I refer to the use of Paquelin's cautery. It is an ingenious instrument by means of which you can keep a point of platinum at a nearly white heat for almost any length of time. The ordinary cautery instruments cool off too quickly, but in this one the fire is maintained by the combustion of the vapor of benzolene. So you can touch the part you wish to cauterize with this heated point, and yet do it very lightly and without making deep eschars, and often with but little pain. The value of this form of counter-irritation is very great, and it is extremely so in those cases of neuralgia which are due to a neuritis, and in inflamed joints of this kind, and in some forms of sciatica. And I have known it to act in quite a magical way in relieving pain and restoring motion in joints which had become stiff and immovable as a result of a sciatic neuralgia.

This, gentlemen, is the case of rheumatic arthritis in the knee-joint, which I showed you a number of weeks ago. She has been treated by the method of counter-irritation, which we have

found extremely useful here for such affections. Applications of Paquelin's thermo-cautery were made to the knee every two or three days for a couple of weeks, and each application was followed by great relief from the tenderness, pain, and swelling. After the swelling had thus been considerably reduced, the joint was forcibly straightened while the patient was under the influence of ether; and the synovial surfaces, which had become united by plastic adhesions, were separated by extension of the limb, which was then put up in a plaster splint, and afterwards confined in a bracket, so as to secure a certain amount of permanent extension. Since then she has suffered almost no pain, and there has been but very little tenderness of the joint, and the size of it has been much reduced. It is probable, however, that there is considerable stiffness of the joint, and there may be a permanent ankylosis. But ankylosis of the joint with the limb straightened in this position is much better than if it had been left permanently in the other position. She is improving in her general health, and is much better in every way. Many cases of this character are left to get well with the leg in the position in which you first saw this one. So this case has been instructive in showing you what good treatment can accomplish.

Hysteria.

The next patient is 20 years of age, single, and a factory girl. She was admitted December 13. Her family history is negative as regards chorea, epilepsy, and other nervous disorders. Patient has been employed in a cotton factory, where she worked in a room which was filled with fine dust, and with floating particles of cotton. She has never had chorea, or fits, or rheumatism, or malarial fever. She has not been in the habit of using beer or alcoholic liquors. She is not naturally of a nervous temperament. Has usually enjoyed good health; but she had scarlatina when a child. Eight or nine months ago she fell down stairs and bruised her left tibia, which caused a swelling upon the front part of the leg, and this ended in the formation of an ulcer, which had no disposition to yield. A little over three months ago she had an attack of typhoid fever, and after her recovery the ulcer on her leg, which had previously been very sensitive, ceased to trouble her, and then she suddenly became afflicted with an uncontrollable hiccough, which continued most of the time for nine weeks up to the day of her admission, and which has persisted ever since. Three physicians were called in to see her, and they all pronounced it a hopeless case. The hiccoughing generally comes on in the latter part of the day, and it continues well into the night. Of late the attacks of singultus have increased in frequency and severity, and for the past two days it has been almost unendurable. She hiccoughs twenty-five or thirty times a minute. Now she can not easily swallow even liquid food. She says she has always a full and choking sensation in the throat, as if there were something caught in it. There are no points of tenderness over the cervical vertebræ, or upon the throat, or in the region of the diaphragm. She is very hyperæsthetic over the whole of the surface of the left leg, and especially so over the seat of the ulcer, and at those times when the ulcer is worse the hiccough becomes most severe. Her bowels have been regular, and her micturition normal. None of the other members of her family have ever been similarly affected. She has no cardiac disease. Two months before admission, at the time when the hiccoughing began, menstruation ceased, and it has not returned since, except that there was a slight discharge upon the day of her admission, The pulse, respiration, and temperature were normal at the time of her admission, and they have remained so since.

Gentlemen, I suppose that we shall never know just what relation the manifestation of pain in a hysterical subject bears to the pain itself. I am inclined to think that we are not as lenient as we should be to the sufferings of hysterical patients. There is something so unaccountable about this disease in the minds of the laity, and of doctors as well, that I think much injustice has been done to these patients. Some look upon it as an entirely sham disease, while others more merciful look upon it as a disease involved in much obscurity, but nevertheless worthy of as careful consideration as any other disease.

This young woman gives you the history of some of those various hysterical manifestations which are apt to follow from some violent shock. She had a fall last summer, and subsequently an acute illness. The first manifestation of hysteria after this was a spasmodic one, a singultus which has persisted ever since; and she has also had an hyperæsthesia of the leg, at the seat of the injury especially, and other pains, particularly the globus hystericus. And all these belong to the hysterical phenomena of the disease, which may be defined as a functional disorder of the nervous system that we do not understand. There is no reason to believe that there is here any organic or uterine disease, but somewhere in the nervous system there is doubtless some lesion of considerable extent which is the cause of these phenomena. But singultus is not a very common phenomenon.

This case has lasted longer than any that I have ever seen before. But some time ago I read an article in a medical journal, in which an English physician described a case of singultus which lasted for eight or nine months, and then completely ceased. Since she came into the hospital she has been relieved, sometimes for several days at a time, by dieting and good care. But we have been obliged to take her out of this ward several times because of the disturbance she creates, and this removal from the presence of others to a place by herself always benefits her, and the hiccough ceases. But when she is brought back again, and she becomes conscious that she is an object of general attention, the trouble returns. This effect of being observed is one of the peculiarities of these hysterical phenomena. And I have no doubt that she would go on hiccoughing in this way, as you hear her now, as long as we would stand here about her; and I am also pretty sure that if she were taken into another ward by herself it would immediately subside.

But after all, we must not scold these patients, and tell them that they are shamming, for it would do no good. It is really a disease, and this is one of its features. She has been benefited by

the hospital discipline and diet, and has had days together of complete relief from suffering. Still she has had to take drugs sometimes, to quiet her and lessen the violence of these attacks. The hyperæsthesia of the leg has subsided to a considerable extent since she came in, but it is more tender to-day than it was yesterday. All these symptoms will subside under the influence of nervous sedatives and good nutrition. She is now taking the bromides. The case that I saw last with these symptoms was more benefited by the use of cannabis indica than by any other means. The hypodermic injection of morphia, or the administration of chloroform or cannabis indica, would probably relieve her temporarily; but I have found that cod liver oil and tonics are more especially to be relied upon for a complete recovery.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Pathological Specimens of a Mono-locular Ovarian Cyst, Weight, Twenty-four Pounds; and an Uterine Myoma, Weight, Thirty-five Pounds.

A regular meeting of this Society was held May 19, 1884. The first specimen was exhibited by Dr. Charles T. Parkes, who presented the following history of the case:

The cyst was a most perfect one, removed from a girl aged nineteen, but four days previously. The tumor had been developing undoubtedly for three years, during two years and a half of which she had been treated by several physicians for various disorders, dropsy, etc. Six months ago she consulted him, and an ovarian cyst was diagnosed. This has gradually increased in size, until the abdomen had attained a size of forty-four inches in circumference. There were no symptoms of inconvenience arising from it, except from its large size. She enjoyed good health. Upon palpation and percussion, a simple wave was easily perceived, and this, with other noticeable symptoms present, it was therefore supposed to be a simple, single cyst of large dimension. There were no symptoms of its being polycystic nor that there would be found many adhesions, or that the viscera were involved. In a few moments the cavity of the specimen was inflated with air, and there was noticeable no corrugations, but a most beautifully-developed cyst of the monolocular variety that we have ever seen. The operation for its removal was extremely easily done. An incision three or three and a half inches in length, sufficient to admit three fingers into the abdomen, was made, and the tumor tapped. There was a very broad pedicle, which, however, is characteristic of this variety of ovarian tumor. There were not many segments and but little hemorrhage, which was easily secured with a double ligature. There were no folds of intestine adherent to the cyst, and but a single shred of omentum was involved. Since the operation at no time has there been a rise in the temperature above 99½°F. Her pulse rose to 100, but now ranges in the nineties, and an auspicious convalescence is predicted. The merits of the specimen consist chiefly in its rotundity, as is shown when inflated with air, and its perfectiou in every other respect, as above demonstrated. The sac weighed one pound, and the fluid that was removed weighed twenty-three pounds, or a total of twenty-four pounds.

The second specimen, presented by Dr. E. C. Dudley, who recited verbally the following history, is both rare and interesting: The patient was a Norwegian woman, who never had been pregnant. She is 48 years old, and never has been married; a domestic. The operation for its removal was performed on the afternoon of the 17th day of March of the present year.

History.—She ceased to menstruate two years ago last fall. The tumor had been for a number of years developing, and during the past three or four years the surgeons she consulted stated that an attempt at its removal would result in destroying her life. Dr. Dudley supposed it to be fibroid, having extensive adhesions. The tumor developed in the left side of her pelvis. There was no tympanitis present on this side, but a line of resonance extended for eight or nine inches over the transverse colon. Upon vaginal exploration, the cervix could scarcely be reached, and no outline of the vaginal portion of it could be felt. The tumor was very hard, and by manual examination and other means it was ascertained to be of unusual size. His prognosis was fatal without operation, and with slight hopes of recovery with an operation. The patient took her departure, and in a few days called again to ask the doctor if the operation was surely fatal, when she was answered again negatively. She went away, and in a few days returned the third time to ascertain the possibility of her chances of recovery. She had grown very emaciated and anæmic, and her appetite was greatly impaired, while she presented almost a cadaveric appearance. Her stomach rejected almost all kinds of food. She was at this visit informed that an operation afforded her the only possible chance of prolonging her life and chance of recovery, although at this date her chances for recovery had grown to be much less. So the above day was appointed as the time for the operation, with the able assistance of Drs. R. N. Isham, C. Fenger, W. W. Jaggard, W. P. Verity, George Isham, and a medical student. During the two days previous she had been put in the best hygienic condition possible. She had two Turkish baths, and her system otherwise had received great care and attention. All the furniture, including carpets, curtains, etc., etc., were removed and thoroughly disinfected, and for 24 hours her bed-room was subjected to the influence of fumes of sulphur. Her abdomen was abluted with a weak solution of corrosive sublimate. The hair was shaven from the pubes and vulva. Every possible site where infection could start was carefully guarded against by thorough cleansing of the surroundings, as well as cleanliness to her clothing, linen, etc. The ligatures to be used were boiled in a 95 per cent. solution of carbolic acid for ten minutes, and again in a 5 per cent. solution for half an hour, and the instruments used were subjected to the flame and then carbolized. The operators and all hands were also washed in carbolized water. Then we proceeded with the operation proper.

After she was anæsthetized (ether being used), an incision was made, extending from the umbilicus upwards to within two inches of the ensiform cartilage, which was eighteen inches in length; this was done for fear of cutting into the bladder, for the tumor drew the bladder up to the umbilicus, as it was adherent to the anterior surface of the tumor; and had the incision been made downwards, the bladder would have surely been cut. The urachus was opened, and a spirt of urine followed as a result. A large bundle of vessels that looked like intestines were then severed, which were with some difficulty ligated; and we saw before us the weighty mass which developed from the left side of the uterus, with the broad ligament involved in it. The tumor was severed; there was at least a square foot of surface in all directions. The enucleation was singularly easy; the posterior surface was adherent to the peritoneum, this part being quite firm, but the bladder peeled up easily. One and a half hour of time had been consumed thus far, before the pedicle was secured, which was done by an elastic ligature, consisting of a solid rubber cord one-quarter of an inch in diameter, and placed four times around the pedicle before the tumor was divided, which, as has already been noted, was a foot in diameter. After this was removed, another tumor, the size and shape of a fœtal skull, was discovered, which filled the pelvis minor, and it is wonderful that the functions of the rectum and bladder were not interfered with more than they were. The lesser tumor sprang from the posterior wall of the uterus, and to secure this one a ligature of the same kind precisely was used as was utilized for the larger tumor. This ligature was the size of a man's fist. The large tumor especially was exceedingly vascular. Esmarch's bandage was first applied, but it slipped off, and this part of the operation was found to be impracticable, and consequently considerable valuable time had been lost in essaying to apply this form of bandage. Her pulse was extremely feeble. Indeed, to all appearances, she was nearer dead than alive, and yet the operation was not completed, as a considerable portion of the larger tumor remained, which was with much difficulty removed, and a clamp applied to the pedicle externally, and two drainage tubes inserted while the patient was being revived, and the minor details, closure of the wound, etc. From the first to the eighth day she was conscious. Flatus passed downwards; her temperature ranged from 98° to 101° F., and her pulse from 100 to 120. On the ninth day her temperature rose to 102° in the morning, to 103° F. in the evening. On the eleventh and twelfth days her temperature rose to 104½° F., with an exacerbation of other symptoms. We thought pus was forming in the lower portion of her abdomen, and with the assistance of Drs. R. Tilley and Fenger, this cavity was opened through the uterus, and at least one-half pint of fœtid matter escaped. A drainage tube was passed in through Douglas' *cul-de-sac*. This abscess had formed below the pelvic organs, which was carefully washed out with weak warm solutions of carbolic acid, and within two days a large amount of pus was discharged, and her temperature had reduced two or three degrees. In a few days it again arose to 104½°, pulse 135 to 140, with hectic chills, etc., and a counter opening was made through these parts, when her symptoms again became ameliorated, her pulse keeping about pace with her temperature and respiration, until the 27th day, when the drainage tube through the *cul-de-sac* was removed, and also the smaller sized ligature; there was only slight absorption of the ligature. From this procedure her temperature advanced a little. On the thirty-seventh day after the operation the large double ligature, consisting of the rubber cord, was removed, and a considerable sloughing mass came away with it. After four days more the opening through the womb into the vagina closed spontaneously. On the sixtieth day after the operation, her temperature rose to 101° or perhaps a little above this point. Was hastily summoned to see her. The cause assigned for this state of affairs was that she injudiciously exposed herself to a draft of air the day previously by sitting at the open window. During the succeeding day her temperature rose to 102°, accompanied by considerable fever. However, under suitable measures, on the evening of the sixty-third day after the operation, all her symptoms again improved, and there can be no doubt now as to her final recovery. Throughout the entire treatment of the wound, it was dressed with iodoform insufflations, and the drainage-tubes were at all times carbolized. Of late she has taken a large amount of food three times a day. There is no pallor in her face and lips; she has greatly increased in flesh, and she sleeps well.

This case illustrates a few things. First, that any amount of operating in the pelvic cavity of a patient may be done, and recovery ensue; and that this variety of tumor may be removed as safely as was formerly supposed an ovarian cyst could be. That in operations in the abdominal cavity, hemorrhage is the chief source of danger, although sepsis through the uterus is another danger that we must well look after. Again, regarding ligatures. A silver or silk ligature shrinks. Rubber cords, doubled twice, as explained above, were employed in this case, and their contractile force proved very advantageous. Other complications may arise. The operator stated that in the foregoing case the patient had diarrhœa and a very sore mouth at one time, which required proper measures to overcome.

In the discussion regarding diagnosis of these tumors, and also to differentiate them from other varieties, Dr. Parkes stated this to be a difficult question for doctors to consider. No exact set of rules can be given for this except to investigate what we have to deal with by cutting into them. The symptoms of difference are wide between myoma and ovarian tumor of either monocystic or polycystic variety, but much difficulty may arise in our attempting to decide which variety of the latter we may have. The uterine sound, percussion, palpation, history of case, etc., will enable us to differentiate these growths, unless two or more varieties are blended together. As to an ovarian cyst of moderate size and a multiple fibroma, he thought we could pretty accurately decide which we have before us to deal with. Multiple fibromæ are difficult to remove. He had operated three times for this variety, and all the cases had died. Yet a physician is justified in advising an operation for their removal; and the

chances of recovery are as good as when ovariotomy was performed years ago. Regarding his cases, one of the tumors removed weighed forty-two pounds. The patient lived five days after its removal, and then died of exhaustion. In the other cases he operated upon, there were many fibroids, all of which were removed, but the cases later proved fatal. Dr. Dudley's case was extremely interesting, from its vast size, and the many other points he mentioned. There is no doubt about the pedicle as being an item of great interest in these cases, and it should be secured by the extra-peritoneal method, as Dr. Dudley had done. This fastening of the pedicle outside is the only safe way to secure it, and not by the intra-peritoneal method. The case to which we have all listened with so much interest, will go on record as one of the many great operations of abdominal surgery (followed by success) that have been performed in the United States.

Dr. J. R. Flood spoke of the great interest centered in this case of "Uterine Fibroma," and the operation, which was certainly a triumph in surgery, considering the magnitude of the specimen exhibited this evening.

Dr. G. H. Randell inquired if it would have been practicable to remove the uterus whilst operating to remove this large fibroid growth?

Dr. R. Tilley could bear testimony to the extensive adhesions and extreme emaciation in the case of uterine myoma. Also, that at the time of the evacuation of pus, he thinks at least a pint and a half was discharged within five minutes, and that Dr. Dudley had so much underestimated the quantity, that he felt justified in making the correction.

Dr. L. H. Montgomery inqured of the operator, how much of the incision of eighteen inches in length yet remained open? He also presumed that when this was made, it did not contract as in cases of ovarian cystic tumors, which could be tapped and the fluid withdrawn, and where the incision would be much less in length. This gentleman thought both these cases reported were of so great interest, that inasmuch as the annual meeting of the Illinois State Medical Society was to be held in the city during the week, each of them be requested to present the specimens before that society. He thought these cases should both be placed on record, and that Dr. Dudley especially should have had a written report of his case; but the oral statements which had been tersely given by him undoubtedly embraced the main features of the case.

Dr. J. H. Etheridge inquired what the depth of the uterine cavity was before the operation?

Dr. Dudley closed the discussion by first replying to the questions propounded: First, regarding the depth of the uterus. This was nearly normal, it being only about three inches. Regarding the opening at this date, it has united along its entire length, except a small space only sufficiently large to admit the tip of his little finger. And, further, as the same speaker who made this inquiry spoke about the length of the incision, this was eighteen inches long at first, and did not contract as if the removal had been an ovarian cyst. Extra-peritoneal treatment is sometimes quite impossible to carry out. In his case, nature had assisted in changing the intra-peritoneal of the pedicle to extra-peritoneal, which saved the woman. One thing he omitted to mention in the treatment of this case. It was that a portion of the time it was necessary to insert disinfectant sponges in the cavity; and at one time these were soaked in weak solutions of corrosive sublimate, perhaps only 1 part to 20,000 of water, which is said to be sufficient to destroy germs. Regarding the use of clamps; the white-heated iron and statistics, with reports of Mr. Keith, of Edinburgh; of Hegar, Katenbach, and others, for fear of prolixity, already in this report, the reader already being familiar with the general details pertaining to these, this may, therefore, be omitted.

The Society then adjourned. L. H. M.

Periscope.

Comedones in Children.

In the *Lancet*, April 15, 1884, Dr. H. Radcliffe Crocker says that the following cases illustrate a condition which is not generally recognized as a disease of childhood, the text-books only describing comedones as they occur at puberty and onwards, from which this affection differs in several particulars. I will first relate some cases, and then briefly comment on them. All the cases occurred at the East London Hospital for Children:

George W——, aged three years and a half, came to the hospital in June, 1882, for whooping-cough and an eruption which had existed for three months. It consisted of innumerable black pin's-head-sized papules, with no inflammation round them, which were evidently comedones, and could be squeezed out, but with more difficulty than the ordinary kind, and the necessary pressure was very liable to set up inflammation in their sites, but they did not often inflame spontaneously; the expressed material was firmer and tougher than usual, and microscopically consisted of epithelium, with comparatively little fat. The comedones were massed together on the upper part of the forehead, especially on the right side, extending for an inch and a half into the hairy scalp; there were several patches in the occipital region, and a few on the right parietal. They were mainly in groups, but on the forehead were so closely set as to give it a very dirty, almost black, appearance. The following cases were in infants: Henry A——, aged twelve months; when he was nine months old groups of closely set comedones appeared on each cheek; there were less defined groups under the chin and angle of the jaw. The

child was marasmic and pale. A. M——, aged fourteen months; comedones appeared when he was eight months old, symmetrically grouped on the prominent part of each cheek. The child was brought for rickets.

These are only samples of over a dozen cases that I have seen in my own practice and that of others, so that the condition is probably not a very rare one. The majority were in boys between three and twelve years old; and in addition to the regions mentioned, it was observed extending from the scalp to the eyebrows, in the sulcus behind the lower jaw, on the shoulder, and in girls limited to the temporal regions. In most cases the capsules ceased rather abruptly, and when not too closely set the tendency to group was generally evident. The etiology of this condition is evidently different from that after puberty. The position in most of the boys corresponded with the part where their caps were in closest contact with the skin, naturally suggesting that they had some causative connection; and, on comparison with the cases where other regions were affected, the common factor was found to be warmth and moisture. This was confirmed by a recent case of a girl of three years old with laryngeal obstruction, probably diphtheritic, where after repeated linseed poultices she presented, when I saw her, scattered comedones, mingled with acne papules and pustules, all over the back and the lower part of the chest. This, however, does not cover the whole matter. A short time ago my colleague, Dr. Warner, kindly sent me a brother and sister, the boy with the forehead and scalp affected, the girl with the temples alone involved; further, it was stated that another brother had it in a minor degree, and that there were several boys at the school similarly affected. This is not the only instance I have known of more than one member of a family being affected, and suggests the possibility of some contagious element, probably bacterial, though I have not found any such organism as yet. Possibly other irritants may produce the condition, though doubtless some predisposition is necessary. Comedones in children differ from those of adults in their being mainly dependent on local causes, on their greater tendency to group, and to be more closely set, in their involving the hairy scalp, and, finally, to their being generally readily amenable to treatment, all that is usually required being friction with a weak soft soap and spirit liniment; or a weak sulphur application may be employed in mild cases, preceded by fomentation with very hot water.

Excision of a Portion of Intestine, including Ileo-Cæcal Valve, for Fæcal Fistula.

Dr. C. B. Porter describes this case in the *Boston Med. and Surg. Jour.*, May 15, 1884:

The condition was this: two fæcal fistulæ in right groin, one about one and one-half inches from spine of pubes, and the other about three inches further outside; each about one inch above Poupart's ligament. A bougie was passed into one of the fistulous openings (the one highest up in the groin) emerging from the other opening three inches lower down. This was then cut down upon, the tissues consisting of hard cicatricial masses, and the entire cavity laid open. This cut divided the lower margin of the abdominal ring, and laid open the hernial sac; the incision was then prolonged downwards to expose the whole sac, making a wound through the skin of abdominal wall four inches long. Two openings into the intestine were found, about one inch apart. These were connected by a cut made on the director, dividing the superficial epigastric artery, which was first tied with a double ligature. The opening in the intestine was then seen to be in the ileum and cæcum, just at their union. The finger passed readily into the large intestine, but the attempt to introduce it into the small intestine through the ileo-cæcal valve was impossible, as the cicatricial contraction involved the valve itself, and the opening was not larger than a small lead pencil. The dilator was introduced and this opening stretched, then with the forefinger of the left hand introduced into the opening, a dissection was made to release the intestine from its cicatricial attachments to the abdominal wall, necessitating a section of the muscles from the external abdominal ring outwards for about four inches. This done, the intestine was free from all but its mesenteric attachments. To close up the wound in the intestine, the expediency of cutting out a complete section of the intestine was considered, but was not thought wise, as it would involve removing the vermiform appendix and portions of cæcum and ileum. The cicatricial margin of the opening was trimmed off. The opening then involved about four-fifths of the calibre of the bowel. The edges of this wound were then approximated, but as one side was small and the other large intestine, the edges would not lie together smoothly. To obviate this difficulty a longitudinal cut was made in the small intestine, thus giving a longer edge of cut surface, and forming a sort of oval-shaped wound, which could be approximated accurately to the cut edge of the large intestine. The wound was then sewed up with silk sutures as follows: The needle was entered about one-half inch from the wound, penetrating the peritoneal layer, then traversing the middle layer (muscular) of the gut, and emerging one-eighth inch from the margin of the wound, having left the mucous layer untouched. The needle was then entered at the opposite side of the wound, in a corresponding manner traversing the middle layer, and emerging about one-half inch from the wound. Ten sutures were introduced in this way. When these were drawn tight they rolled in the free margin of the wound, thus bringing two serous surfaces in contact, and turning the cut edge into the interior of the bowel. The intestine was then allowed to fall back in the abdominal cavity, after additional silk sutures had been placed between the previous ones, making twenty in all.

The ring and abdominal opening were then brought together and sewed with fine silver wire, the sutures passing through the peritoneum and fascia of the deeper muscles, but not the skin. The ends were cut short and the points bent over. Five sutures were thus placed. The skin was then united by silk sutures, a large-sized drainage tube, three inches long, being inserted into the abdominal cavity.

A graduated compress of carbolic gauze was

then placed over the wound, and a full Lister dressing surrounding the abdomen and thigh, the whole being confined by a spica bandage, firmly sewed together. The whole operation was done under carbolic spray and all antiseptic precautions, occupying in all two hours and three-quarters. There was but very little hemorrhage, the vessels of the skin being tied before the abdomen was opened. There was no escape of fæcal matter at any time. The tract of the small sinus first opened was thoroughly curetted before any other cut was made.

The condition of the patient was excellent throughout, the pulse being full and moderate. About one and one-half pints of ether were used. Recovery ensued.

Cerebral Physiology.

The *Lancet*, April 5, 1884, says: "At a meeting of the Royal Society held on March 20th, Messrs. Victor Horsley and Edward Albert Schäfer read a preliminary communication on the functions of the marginal convolution. The communication was the first of a series giving the results of an experimental investigation into the physiology of the cerebral cortex and its connection with other portions of the nervous system. The animals employed were monkeys, most of them, if not all, some species of Macacque. In some the portion of the brain under investigation had been stimulated by the interrupted current and the resulting movements recorded; in others the cortex had been removed over the region in question (by means of the galvanic cautery and under antiseptic precautions), and the resulting pareses of voluntary movement observed. The authors have for the most part throughout their experiments taken care to employ an excitation just sufficient to call forth the activity of the brain immediately under the electrodes. The mesial surface of the hemisphere, or rather only the marginal convolution of that surface, has been explored, for it soon became evident that positive results were not to be expected from electrical excitation of the other parts of the mesial surface. A remarkable relation was found on the whole to hold good between the different parts of this convolution and the parts of the body thrown into movement by their excitation. Thus it was found that when the stimulus was applied anteriorly, the resulting movements affected the upper limbs; when applied near the middle of the excitable part of the convolution, the muscles chiefly affected were those of the trunk; whilst when applied posteriorly, the muscles of the lower limb alone were called into action. It is further thought probable that the movements which are produced by stimulation of points which succeed one another from before back, take place in the following definite order, viz., movements of the forearm, movements of the humerus and scapula, movements of the upper part of the trunk, movements of the lower part of the trunk, movements of the pelvis, of the hip, at the knee, at the ankles, and, lastly, at the toes. The authors have further produced complete hemiplegia in monkeys by removing the excitable portions of the frontal and parietal lobes of the external surface, in addition to the excitable portions of the marginal convolution. The paralysis resulting from this operation affected not only the muscles of the limbs, but also those of the head and neck and of the trunk; whereas in animals in which only the excitable portions of the external surface (the motor regions of Ferrier) have been removed, the paralysis is but partial, and confined chiefly to the muscles of the limb. Mr. Horsley advocated the theory that in ordinary hemiplegia resulting from hemorrhage in or part outside one corpus striatum, the trunk muscles escaped because the nerve fibres from their part of the cortex (about the marginal convolution) were the last to get damaged by the extravasated blood. He argued that the bursting of the 'artery of hemorrhage' would first place *hors de combat* the facial fibres, then the brachial, next the crural, and, lastly, or not at all, the truncal fibres; the recovery of the function of these parts took place in the inverse fashion. Further, Broadbent's theory of the bilateral association of spinal nuclei was explained by supposing that in a *discharging* lesion affecting only one hemisphere, it was more reasonable to suppose that the energy would spread the shortest way—*i. e.*, to the opposite cortical area."

Hæmaglobinuria.

There are many obscure cases of hæmaglobinuria, in which it is next to impossible to discover any cause to which the disease might be attributed. At the last German Congress for internal medicine, Dr. H. Schumacher, of Aix-la-Chapelle, drew the attention of the profession to the fact that according to his observations all such cases are caused by syphilis. Notwithstanding the apparent mildness and trivialness of the symptoms, experience had proven to him that the complaint is not only a very grave, but finally invariably, also a fatal one. One case, seen by him in the earliest stage, was subjected to an anti-syphilitic treatment and recovered. But such a favorable result is possible only in the beginning of the disease; later, no remedy will influence the course and prevent the fatal issue of the malady.

This observation of Schumacher coincides with our own. It seems that hæmaglobinuria, if due to syphilis, may be recognized by the following peculiarities. The disease attacks the individual without warning; rarely some slight pain in the back may precede it. There is a total absence of all other symptoms. The most careful examination fails to reveal the least lesion, the least disturbance of general health. It seems to be impossible to elicit any etiological moment. This fact, combined with the healthy appearance of the patient, then the impression which the physician gains that the symptom apparently is without influence on the general system, the absence of fever and of all other signs of disease, are the sure evidences of the syphilitic origin of the complaint. To be sure, the presence of the peculiar dirty-yellowish discoloration of the skin of the forehead, of cicatrices of syphilitic ulcers, or of any other syphilitic manifestations, will as rapidly clear up all mystery, as the admission of the patient of his having suffered from constitutional luës. If not treated specifically in the earliest stages, the hæmaglobinuria will come and go, varying greatly in degree, until some other symptom (depending upon the organ next visibly affected) be-

comes added to the hæmaglobinuria. But from this moment all hope for the patient is gone. Brain, heart, lungs, or liver, may become next involved. In the later stages, the disease is apt to be mistaken for cancer of the kidneys, and those cases of cancer of that organ, which have apparently been cured by iodide of potassium and mercury, have doubtless been such of syphilitic origin.

Reflex Nervous Phenomena from a Parasite in the Thigh.

The Paris correspondent of the *Brit. Med. Jour.*, May 10, 1884, says that M. A. Robin relates an interesting case which has recently come under his notice. The patient, an inhabitant of Rio Janeiro, one day suddenly felt a violent pain in the thigh, which quickly passed off, but reappeared on the following day; and at the same hour, simultaneously with the pain, a small purple pimple appeared. The medical men at Rio Janeiro diagnosed it as a carbuncle; but it continued to increase in size without presenting any sign of suppuration. The patient decided to go to Paris. During the journey the pains became especially acute; they appeared in the morning and late in the night; she described them as pinching, burning, dragging pains. Towards the end of the journey, they attacked the stomach, head, and limbs. The patient then suffered from convulsions; after these fits, trismus frequently set in. Several physicians in Paris diagnosed the condition as nervous, and considered the tumor to be unimportant. M. Robin commenced by trying to ascertain the nature of the tumor. He observed a small orifice at its centre, but there was not the slightest indication of suppuration. On pressure, a small mass was expelled, which resembled the core of a boil, and, when carefully examined, was observed to present spontaneous movements, due to the presence of a larva, which M. Laboulbène pronounced to be that of a dipterous insect, *Dermatobia noxalis*, a species unknown in France. After the expulsion of the larva, the nervous attacks ceased, and the patient is now completely cured. M. Megnin quotes the history of a similar case communicated to him by Dr. Josseaume. The larva M. Megnin believed to belong to the same species as that described by M. Laboulbène, which he considered, however, to be the larva of a gad-fly well known in France. M. A. Robin does not agree with M. Megnin. The body of the insect examined by M. Laboulbène was different from that described by M. Megnin, who assured M. Robin that the exterior aspect of the insect is unimportant, and is frequently decided by age.

Diarrhœa in Children.

Dr. Lees, in his paper in the *Med. Times and Gaz.*, May 3, 1884, calls attention to a class of cases, not very uncommon in children, in which the main symptom is an irresistible impulse to defæcation, experienced almost immediately after food has been taken. Colic pain may, or may not, be present, but there is no sensation of weight at epigastrium, heartburn, flatulence, or other symptom of dyspepsia. The motions are usually semi-solid, not often watery or slimy, and frequently contain undigested food. Usually a motion is passed almost immediately after every meal, and perhaps once or twice more during the twenty-four hours. Dr. Lees points out that these symptoms are evidently due to a hyper-peristalsis of the alimentary canal, without increase of secretion, the two factors of ordinary diarrhœa being here disassociated. Such increase of peristalsis, is probably due to irritation of the vagus nerve, which supplies the excitor fibres to the intestine, the splanchnics conveying the inhibitory fibres. The proximity of the nucleus of the vagus to that of the trigeminus, in the medulla, indicated the possibility that this increased excitability of the intestine may in part be due to dental irritation, the cases in question usually occurring during the period of the second dentition. Believing in the purely neurotic origin of the symptoms, Dr. Lees has treated several cases with bromide of potassium simply, without opium or any astringent, and had obtained immediate success, even in cases which had persisted for several months. The diarrhœa was usually arrested in a few days, and occasionally the children became so costive that the medicine had to be discontinued. Four cases were narrated, also a similar case occurring in an adult, in all of which speedy relief was given by bromide. In conclusion he remarks that individuals who suffer from these symptoms are often of a markedly neurotic temperament, timid, and easily frightened.

Complete Dislocation of the Scapula.

The *London Med. Record*, May 15, 1884, tells us that Dr. Böing, of Dinslaken, reports to the *Berlin. Med. Wochensch.* of October 22, 1883, a case of complete dislocation of the scapula which occurred in his practice. The patient had been caught by the projecting handle of a wheel, and pressed against the edge of an iron upright belonging to the machinery, which had inserted itself under the inferior angle of the scapula, and had pushed the bone forwards under the pectoralis major. When first seen, the patient had a decided hollow where the right scapula with its muscles ought to have been, and the bone was entirely covered by the pectoralis major, only the tip of the inferior angle being discovered on careful palpation. There was no cutaneous wound, only a red mark where the edge of the upright had pressed. The hand could be pushed under both the latissimus dorsi and the pectoralis major, but the only place where tenderness was complained of was the inferior angle in the before-mentioned position. Reduction was easily effected by raising the arm, the trunk being firmly fixed, and using the acromion as a fulcrum, when the scapula slipped suddenly back to its normal position, with the same sound as when a joint is put into place. No muscular laceration could be made out. The first rib was then found to be fractured about the middle, evidently from muscular action, as the fragments projected outwards, and it could not have been the result of direct violence. The fracture caused a wound of the lung, which set up traumatic pneumonia; but in sixteen days the patient was able to go about again, and in a month he was back at work.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a recent reprint, Dr. B. F. Baer, of Philadelphia, refutes the popular belief that flooding at the change of life is physiological, and hence rather beneficial than otherwise. He is of the opinion that it is usually the result of uterine disease, hence it demands the attention of the physician as much then as at any other time.

——A sheet or broadside, arranged by Dr. Louis Lewis, showing the condition of the urine in disease, has been published as a supplement to the *Medical World*, Philadelphia. It is handy and perspicuous. Price, 50 cents.

——Dr. Robert M. Smith's paper on the rapidity of the circulation of the blood, to which we have before referred, appears in a neat reprint from the Transactions of the College of Physicians.

——The address on Practical Medicine, read by Dr. John V. Shoemaker at the meeting of the American Medical Association, makes a pamphlet of sixteen pages. It briefly describes some of the most interesting novelties in therapeutics and pathological researches.

——The symptom of unnatural sleepiness occurs in numerous diseases, and its precise significance deserves careful consideration. This it receives in a paper by Prof. C. L. Dana, M. D., of New York city. He cites many extraordinary examples, and traces them to their pathological causes.

——A fertile writer on nervous diseases is Dr. C. H. Hughes, of St. Louis, the editor of "The Alienist and Neurologist." His observations are marked by acuteness and depth.

——We have received from M. P. Chapoteaut a paper introducing to notice a glucoside of boldo, which we should judge would prove a valuable form of the drug.

——Dr. G. Beck's "Therapeutischer Almanach" for 1884, contains its usual large number of condensed notices of remedial novelties. It can be had through E. Steiger & Co.

——Our fellow-townsman, Dr. F. E. Stewart, has devoted much attention to improving the relations between physicians and pharmacists. His latest contribution is entitled, "How Can Physicians Aid in Elevating the Profession of Pharmacy." In this he urges that druggists should give more attention to the scientific aspect of their vocation. They should not sell proprietary remedies. They should practice pharmacy in a liberal spirit, serving science first and commerce afterwards. Such recommendations are more praiseworthy than practical, yet it will do no harm, and perhaps some good, to give them a hearing. The competition of business is pretty sure to be the ruling motive after all.

——The singular symptom of automatic action during inebriety is illustrated by Dr. T. D. Crothers, of Hartford, Conn., in a recent reprint. The cases he quotes are highly instructive.

BOOK NOTICES.

Health Hints for Travelers. By John C. Sundberg, M. D. Price, 50 cents, cloth. Published at the office of the Medical and Surgical Reporter, Philadelphia.

A few years ago the author of this convenient little book was attached to this journal. His wide travels led him to the belief that much of the suffering and ill health to which travelers are exposed arises from an ignorance of simple sanitary laws and elementary points in medicine. These he has aimed to group together in a style at once easy to read and facile of comprehension. From our examination of his work we heartily commend it as containing a great number of suggestions well worthy the consideration of travelers. It will form the most valuable piece of baggage of its size that they can stow in their grip-sack.

One point the author brings out forcibly, and that is, that in traveling a person acquainted with some of the simpler resources of practical medicine can frequently relieve many others from the annoyances and even the pains which exposure to new surroundings often involves. We should be glad to witness a wide distribution of Dr. Sundberg's work among the traveling public.

Medical German. A Manual Designed to Aid Physicians in their Intercourse with German Patients, and in Reading Medical Works and Publications in the German Language. By Solomon Deutsch, Ph. D. Pp. 336. J. H. Vail & Co., New York City.

A practicing physician once informed us that by actual count his knowledge of German had added to his business an amount equal to the interest on $10,000 every year. His case was no exception. It is certainly much the most useful language outside of English in this country. The manual above named appears to be thorough and practical. He arranges the medical terms systematically with reference to the different parts of the body and the various diseases. We doubt not that it will be found a valuable aid to those who would perfect themselves in this useful tongue.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,

PHILADELPHIA, PA.

DA COSTA'S
Medical Diagnosis
(LATEST EDITION)
FOR ONE DOLLAR!

This invaluable standard work by the eminent professor of practice in the Jefferson College, (published by J. B. Lippincott & Co., cloth, price $6.00), will be sent postpaid to any subscriber of the MEDICAL AND SURGICAL REPORTER, for *one dollar*, and the name of a new subscriber who agrees to pay for one year's subscription ($5.00) to the REPORTER within 30 days.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

LEGAL VIEWS ABOUT CREMATION.

The question of cremation has been revived lately by a variety of events, among which are the incineration of the body of the late Professor Gross, and the discussion in the English Parliament over a bill legalizing cremation.

This bill failed to pass; but in view of a recent decision in one of the English courts, it would seem that this mode of disposing of the dead is hardly illegal. This case involved the two questions of cremation as a misdemeanor before the common law, and as preventing an inquest. It will at once be seen that incineration will absolutely destroy the evidences of poisoning, or violent death, and in some cases justice might be prevented if cremation could be adopted at the will of the dead man's friends or enemies, as the case might be.

To this it will be answered that the laws requiring the registration of the cause of death by a reputable physician would prevent the body being put at once beyond the power of examination. But this will not answer the case fully; for the penalty for burying a body without a certificate is in general slight, and the same would apply in cases of cremation. A person guilty of murder might at once burn a body, making himself liable to the smaller punishment to save the greater; and if the entire evidence of the crime consisted in the proof furnished by the body, it would be practically impossible to secure a conviction, no matter how suspicious the circumstances seemed to be.

At the same time, it must be remembered that the right of a coroner to hold an inquest is not an absolute one. He can never interfere with the ordinary preparations for a funeral, without reasonable grounds for believing that the circumstances connected with the death are unusual. If he does thus interfere without good reason, he becomes liable to an action.

In the English case referred to, a man named Price was directed to file a certificate of the cause of death of his five-months-old child, and was informed that an inquest would be held in case this was not done. The certificate was not filed, and

before an inquest could be held, he attempted to burn the body by placing it in a cask of petroleum, which he set on fire. The neighbors extinguished the fire with earth, though the case does not say whether the body was burned sufficiently to prevent an intelligent examination into the cause of death. Price was then arrested and indicted for committing a misdemeanor in attempting to cremate the body, and on the further charge of preventing an inquest.

On both of these charges the jury acquitted him, showing that in the view of the jurors the death was a natural one.

The court discussed the whole matter quite at length, holding that cremation *per se* could not be considered a misdemeanor. The law contemplated in all its decisions burial, but that seemed to be the case, because cremation was not, in the minds of the judges; and without some declaration on the part of Parliament, the courts would not decide that cremation was illegal. It was, however, decided that the mode of cremation might be so public and annoying as to make the act a nuisance, for which a man might be properly indicted. The burning attempted by Price was on his own land, and presumably not of such a character. It has been claimed that every person was entitled to "Christian burial," but these expressions in the law-books were used at a time when cremation was unknown in England. The court declined to express any opinion regarding the propriety of cremation, but said that in the present state of English law the act could not be considered criminal.

What effect the failure of Parliament to act on the matter will have, remains to be seen; but it is reasonably certain that at some time cremation, under certain restrictions, will be allowed by positive enactment.

The English people are exceedingly conservative, and their persistent refusal for so long to permit marriage with a deceased wife's sister shows that any measure looking towards the substitution of cremation for burial will be delayed a long time.

Cremation societies exist in this country, and seem to be increasing in number, although as yet there is but one crematory—that at Washington, Pennsylvania.

THE RESPONSIBILITY OF SURGEONS.

The important question of a surgeon's responsibility in cases of accident was brought up in an unusual way in a recent case in an Illinois court.

A person was injured in a railroad collision, and in a suit against the company for damages it was alleged in defense that the plaintiff had himself been negligent. The principal ground for this claim was not any negligence at the time of the accident, but a subsequent negligence in choosing an incompetent surgeon to attend him. The interesting point of the liability of the surgeon under these circumstances was not considered, but the court held that the claim, if true, was no defense to the action against the company. The verdict against the railroad people was therefore sustained.

A portion of the opinion of the court will be of interest, and is as follows:

"There is evidence tending to show that had this broken arm received ordinary care and ordinary professional skill, the parts would have united with little or no permanent injury, and on this hypothesis alone appellant insists that the matter of this false joint should have been, at least hypothetically, excluded from the jury. We understand the law on this subject to be that plaintiff cannot hold defendant answerable for any injury caused, even in part, by the fault of plaintiff in failing to use ordinary care or ordinary judgment, or for any injury not resulting from the fault of defendant, but caused by some new intervening cause not incident to the injury caused by defendant's wrong.

"Thus in this case, if it be conceded that the false joint, under proper care and skill, would not have resulted from the breaking of the arm alone, but was brought about by the subsequent separation of the parts after they had been properly set, and before nature had formed a firm union, then if this subsequent separation of the parts had been caused by an assault and battery by a stranger, or some foreign causes with which appellant had no connection, and which was not in its nature incident to a broken arm, plainly appellant ought not to be held to answer for the false joint; but if appellee exercised ordinary

care to keep the parts together, and used ordinary care in the selection of surgeons and doctors, and nurses if needed, and employed those of ordinary skill and care in their profession, and still by some unskillful or negligent act of such nurses, or doctors, or surgeons, the parts become separated, and the false joint was the result, appellant, if responsible for the breaking of the arm, ought to answer for the injury in the false joint.

"The appellee, when injured, was bound by law to use ordinary care to render the injury no greater than necessary. It was therefore his duty to employ such surgeons and nurses as ordinary prudence in his situation required, and to use ordinary judgment and care in doing so, and to select only such as were of at least ordinary skill and care in their profession. But the law does not make him an insurer in such case that such surgeons, or doctors, or nurses, will be guilty of no negligence, error in judgment, or want of care.

"The liability to mistakes in curing is incident to a broken arm, and where such mistakes occur (the injured party using ordinary care) the injury resulting from such mistakes is properly regarded as part of the immediate and direct damages resulting from the breaking of the arm."

These views will commend themselves to the good sense of most readers, and strike us as a fair presentment of the points.

A NEW DISEASE.

We had lately occasion to refer to Virchow's discovery of the actinomycetes, which cause the same chalky deposits in the muscular tissue of the hog, as do trichinæ. Dr. Zemann has recently observed five cases of actinomykosis in human beings. These cases seem to throw some light on this obscure disease.

In four of the five cases the disease began with lancinating and cutting pains in the abdomen, and in its further course exhibited the picture of a slowly-developing, a febrile, low typhoid condition, due to chronic peritonitis. In one or more places of the abdominal wall local swelling set in, ending in abscess formation with external discharge of the pus, but frequently communicating with a perforated intestine. In one of these cases the characteristic nodules were detected during the lifetime of the individual. The fifth case happened in a strong and healthy person, and here the disease ran its course as an acute, febrile malady, which on account of the brain symptoms accompanying it, was diagnosticated as meningitis. In all the five cases the disease began in the abdominal cavity, and there in the peritoneum, to which it was limited, and in but one case metastatic abscesses in the liver were observed. The peritoneal covering of the intestines was extensively diseased; affections of the bones were met with in none of the cases, and the spinal column did not evince the least indication of its participation in the morbid process. But some organs were attacked, which had not suffered in any cases thus far published. Twice the bladder was found perforated by mykotic ulcerations; once the disease spread from the neighborhood to the left ovary, and in one case one Fallopian tube was diseased, and found the real and only seat of the morbid lesion. In the latter case, where the intestines were perfectly normal, the infection, in the opinion of Z., had probably taken place by way of the vagina, while in the other four cases the micrococci entered by the alimentary canal.

Concerning diagnosis, the pathognomonic nodules of the parasite form the only sure indication of the disease; without them the diagnosis is impossible, for the disease may be febrile and acute, or febrile and chronic, it may present the picture of a phlegmon, of chronic inflammation of serous membranes, or of inflammation of bones or periosteum, or that of internal organs; and as the entrance of the parasite into the body may happen anywhere, and as the inflammation usually attacks the place of entrance, and is not always limited to it, the possible complications that may arise can not be calculated.

TUBERCULOSIS VERSUS CONSUMPTION.

The question of identity of the two pathological processes, known the one as tuberculosis and the other as consumption, was recently brought before an alderman of this city, and this judicial functionary was requested to decide. This incident, trivial and ludicrous as it may seem, points out with unusual clearness the necessity of an unanimous opinion among the members of the

medical profession as to the identity or dissimilarity of the two diseases.

The facts in the case, stripped of all unnecessary details, are as follows: A young man suffering from constitutional syphilis takes out a policy with a beneficial society, paying ten cents a week premium. The policy contains a clause to the effect that if the holder of it dies of consumption within a year from date, the family is entitled to but one-half of the amount of the insurance. This young man died of acute general tuberculosis ten days before the expiration of the year, and the company pays but half the amount of the insurance. The widow, however, sues the company for the other half, and on the testimony of the attending physician, who by the way believes in the individuality of tuberculosis and phthisis, the alderman decided in favor of the plaintiff. In other words, the burning question of the identity of phthisis with tuberculosis was decided in the negative.

The expert testimony, as well as that of the attending physician, went to show that the term "consumption" used in the policy is too vague, and covers too much ground in a scientific point of view; and at the same time it elicited that the popular interpretation of the word was that it meant destructive lung disease only. Since in the case in question the lung symptoms had been very slight, and were altogether overshadowed by the symptoms of tubercular deposits in almost all the other organs of the body, the magistrate was certainly in the right to deliver his decision for the plaintiff.

Notes and Comments.

Black Tongue.

The following case of this affection, which Dr. G. T. Broatch reports in the *Brit. Med. Jour.*, April 19, 1884, may prove interesting to our readers:

The patient is a man aged sixty, a painter and glazier by trade, but, on account of ill-health, has not done any work for seven years. Shortly after he commenced his apprenticeship, he was attacked with lead-colic, and the blue line characteristic of lead-poisoning appeared on his gums, and remained for about twelve months. He has never enjoyed robust health, and at present suffers from ulcers on his legs, which have existed for the last thirty years.

On examination of the tongue, the blackness is seen to be in the form of a circular patch, about an inch in diameter, situated at the posterior third of the dorsum. The greater part of it is of a deep black color, while at the margin it is lighter, being brownish; and surrounding this for about half an inch there is a whitish tinge. Behind the coloration are a number of light-colored nodules in the position of the circumvallate papillæ. The other parts of the tongue, except being slightly fissured, are normal. Upon stroking the patch with the finger from before backwards, it feels soft and smooth; while, on reversing the motion, it feels roughish, this being caused by the finger passing over what looks like a mass of black hairs. The discoloration is entirely composed of these black filaments, some of them of considerable length, with shorter ones intermixed. They can be detached easily with dressing-forceps, bringing along with them a portion of the subjacent tissue, which is light in color. The blackness commenced about two years ago, the patient feeling, as he describes it, as if his tongue were too large for his mouth; and, on examining it, he found a small discolored spot, which has gone on extending ever since. He has no pain in the tongue, nor any diminution in his sense of taste.

On microscopical examination of one of the filaments, it is seen to be composed of epithelial cells of a brown color, closely packed, and overlapping one another. In some cases, the centre of the filament is very dark, with a lighter margin; and in other cases it is the reverse. When the latter condition occurs, there appears to be a tendency for it to split down the centre. On examination from the apex of the thread downwards, the color gradually becomes less, till, at the point where it springs from the tongue, no staining of the cells can be detected. These filaments appear to be, as stated in the article by Mr. Stoker, the fringes of the papillæ greatly hypertrophied, and their cells stained of a brown color.

The Hot-beds of Yellow Fever.

Dr. Domingo Freire (*El Siglo Medico*, December 9, 1883), commissioned by the Brazilian Government to inquire into the origin, prophylaxis, etc., of yellow fever, found on examining the earth from the cemetery of Jurujabù, where those dy-

ing from yellow fever in the Marine Hospital of St. Isabel were interred, that the soil was swarming with the same micro-organisms which exist in the vomit, blood, and urine of patients suffering from the disease. The soil was taken from the grave of a person who had died the year before, at the depth of one foot from the surface. In appearance, smell, and other characters, it presented no peculiarities, but, on examination under the microscope, with a power of 740 diameters, myriads of micro-organisms were seen, identical with those found in the organic liquids of the fever patients. These organisms are the cells of the *Cryptococcus xanthogenicus* in various stages of development, varying in size from a scarcely perceptible black point to more or less large round corpuscles, highly refractive, grey or black, or encircled with a black fringe or areola. Many of these organisms made spontaneous movements. Yellow masses spotted with granulations, due to the coloring matter of the cells, and black points, the remains of the cryptococci, were also seen, as were some rapidly moving vibriones. These observations, which were fully confirmed by Señores Chapot, Cæsar, and Caminhoa, show that the germs of yellow fever are perpetuated in cemeteries, which are so many hot-beds or nurseries for the cultivation of new generations destined to devastate the country. He recommends the removal of cemeteries to remote parts, or, better still, cremation.

To Remove Foreign Bodies from the Eye.

Before resorting to any metallic instrument for this purpose, Dr. C. D. Agnew (*American Practitioner*, May, 1884,) would advise you to use an instrument made in the following manner: Take a splinter of soft wood, pine or cedar, and whittle it into the shape of a probe, making it about the length of an ordinary dressing probe. Then take a small, loose flock of cotton, and, laying it upon your forefinger, place the pointed end of the stick in the center of it. Then turn the flock of cotton over the end of the stick, winding it round and round, so as to make it adhere firmly. If you will look at the end of such a probe with a two-inch lens you will see that it is quite rough, the fibres of cotton making a file-like extremity, in the midst of which are little interstices. As the material is soft, it will do no harm to the cornea when brushed over its surface.

When ready to remove the foreign body, have the patient rest his head against your chest, draw the upper lid up with the forefinger of your left hand, and press the lower lid down with the middle finger, and then delicately sweep the surface in which the foreign body is imbedded, with the end of the cotton probe. When the foreign body is lodged in the center of the cornea, it is most important not to break up the external elastic lamina; for if you do, opacity may follow, and the slightest opacity in the center of the cornea will cause a serious diminution in the sharpness of vision.

Glycerine and Codeia Jelly.

In the *Brit. Med. Jour.*, April 19, 1884, Dr. G. S. Mahomed draws the attention of the profession to a preparation consisting of codeia with citric acid, tolu, and glycerine, which he thinks will be found a pleasant and serviceable agent in the treatment of chronic laryngitis, phthisical cough, etc.

He had lately to treat a lady suffering from laryngeal catarrh. During the defervescence of her attack she was much troubled by thirst, dryness of the fauces, and consequent cough and sleeplessness. It appeared to him that if he could get the mucous membrane back to its normal state, instead of the dry, hyperæmic, concentrated-viscid-mucus-secreting condition into which it had fallen, the cough would vanish. We have often to deal with a similar condition in phthisis.

Of all agents, glycerine, both from its mechanical and hydroscopic properties, would be the most suitable for such a purpose; and the comfort obtained from oranges or lemon-juice, under such circumstances, is well known. He thought codeia would be the least noxious sedative, and that something in jelly-form would remain longer in contact with the parts. The jelly is flavored with lemon, and very pleasant to take; and he thinks many will agree with him in thinking that it is often preferable to order such a preparation, particularly in long and intractable cases, to writing fresh prescriptions. Patients take them more readily than ordinary medicines, and, if unrelieved, are less prone to be discouraged.

Certain Contra-Indications in Medicines.

Dr. Rabuteau has made the observation, that certain medicines which, administered alone, cause no disagreeable symptoms, usually produce them when given in connection with other drugs, which by themselves neither induce such phenomena. It is, therefore, their combination which at times must be avoided. We select from his observations (*Fortsch. d. Med.* 9, 1884) the following two, as they concern remedies which are very generally

employed; in one of them it is this combination, and in the other the time, at which the drug is administered which brings about the unusual effect.

Nausea, vomiting, gastralgia, and colic have been observed, when iodide of potassium and sulphate of quinia are prescribed together. The same phenomena have been noted, when iodides and bromides are employed at the same time. In both cases iodine is set free, and the peculiar action of such combinations has to be ascribed to this fact. Quinine is contra-indicated during the period of menstruation. Female patients who at any other time do not suffer from disagreeable effects of the drug, complain of intense pains in the hypogastric region if they take the same doses of quinine that had been administered to them at some other time without disturbance, during the menses. It is well known that quinine causes irritation of the uterus. As the irritability of this organ is usually increased at the time of the monthly period, the occurrence of labor-like pains ensuing upon the internal administration of quinine can thus be easily explained.

Gastrostomy.

A remarkable operation of this kind was performed by Mr. Knowsley Thornton, of England, on May 6, at the Samaritan Hospital. A girl, aged 18, had indulged for some years in the habit, not unknown in the records of clinical medicine, of eating the combings of her hair, and swallowing cotton and other like materials. A large mass gradually collected, which was moulded into the shape of the stomach, and measured nine and a half inches in length, and five in breadth at the cardiac end. The stomach was opened on its anterior surface by an incision five inches long. Very little hemorrhage ensued, and the mass was extracted by means of a vulsellum. During this process, precautions were taken so that neither the wound nor the peritoneum was fouled by the contents of the stomach. The wound was closed by five silk sutures, deep and superficial, interrupted and continuous. A case of a similar kind, which terminated in the recovery of the patient, is recorded by Schönborn in Langenbeck's *Archiv.*, vol. xxix, 1883, page 619.

A New Remedy for Diphtheria.

The Medical Society of Hospitals in Paris in its meeting of May 9, this year, debated the treatment of diphtheria. Nothing new was brought up save a peculiar method employed in Delthil's clinic. D. burns in the sick-room an equal mixture of coal-tar and ol. terebinthinæ, causing the formation of thick, black vapor. The air of the room becomes impregnated with carbon in various combinations, and the latter are said to dissolve the fatty substances which unite the constituent parts of the diphtheritic membranes. In consequence of this chemical action it is believed the membranes lose their tenacity and their adherence to the tissues, and their expectoration is easier.

D. tried this method on four children, on whom on account of laryngeal diphtheria tracheotomy had been performed. Three of the patients died. But remembering the fatality usually attending cases of this kind, the result is, if anything, favorable. Dr. Féréol employed the same treatment on an adult, suffering from a mild type of the same disease. After each fumigation, which was very well borne by the patient, free expectoration ensued, and on the second day the membranes had become soft and were much less adherent. (*Deutsch, Med. Z.*, May 22, 1884.)

Operation for Strabismus.

It is not always easy to decide at what time the operation for strabismus should be made. The effort which Dr. J. Hock, lecturer at the Vienna University, recently made (*Deutsch. Med. Z.*, p. 449, 1884) to determine the time best adapted for this purpose, throws for the first time some light on this important subject. H. has come to the following conclusions. The operation should be performed:

In cases of convergent strabismus—

1. Immediately after the first appearance of squinting, *i. e.*, within a few hours or days.
2. During the stage of periodical squinting.
3. As long as regular diplopia is manifest.
4. In cases of relative squinting at any time.
5. In constant, inveterate squinting it is all the same when the operation is performed, its purpose being but cosmetic.

In cases of divergent strabismus—

1. As long as regular diplopia is present.
2. During the stage of relative squinting, but with the above limitations.
3. In cases of exclusion if the patient demand the operation.

Symptomatic Hemichorea.

A soldier, æt. 23, for some time psychically affected (hallucinations, fear of being persecuted, etc.,) was seized with right-sided hemichorea. This increased gradually, a true "folie muscu-

laire" of the right half of the body developed itself, accompanied by unconsciousness, often lasting for several hours, and soon after death set in. Besides opacity and thickening of the meninges in the fronto-parietal regions of both sides, especially on the left, softening, due to hemorrhage, was observed in the posterior crus of the internal capsule on the left side, spreading over the neighboring parts of the thalamus opticus and the corpus striatum. As a remarkable fact may be stated that neither hemiplegia nor hemianæsthesia was noted during the progress of the disease. What caused the hemorrhage could not be explained, neither syphilis, nor atheroma of the vessels, nor vitium cordis being present. (*Revue de Med.*, 6, 1884.)

Dropping Fluids into the Eye.

We had but recently the opportunity of watching the dropping of a borax solution into the eyes of a child suffering from catarrhal conjunctivitis. The child cried vehemently, for the physician opened the lids with his fingers and thus dropped the fluid into the eye—a procedure, if not painful, at least very disagreeable. It may, therefore, not be amiss to mention the following by far better method.

The inner corner of the eye is first cleaned from all impurities, and then thoroughly dried. While the child is in the recumbent position, the eye is kept closed. One or two drops of the fluid, indicated in the case, are then dropped into the corner. When the child opens the lid, the drops flow slowly into the eye. Should the child be asleep, or not at once open the eye, the operator needs but slightly to separate the eyelids, when the drops will immediately enter.

Chronic Mercurial Poisoning.

Two interesting cases of chronic poisoning by mercury have recently been published by Dr. Neukirch (*Berl. Klin. Wochenscrift*, 15, 1884). The important point in both cases is the fact that they were caused by the bad condition of the mercurial covering of a mirror, and that they were induced in this manner has been proven beyond a doubt. After removal of the mirror from the room, the morbid symptoms soon ceased. The diagnosis was verified by the discovery of rather large quantities of hydrargyrum in the urine of the patients, who presented besides all the usual symptoms of chronic mercurial intoxication. None of them had been using any purgative pills, nor any other medicine, nor any substance containing mercury. Moreover, the immediate improvement ensuing after removal of the patho genic cause, leaves no doubt whatever.

A Modification of Syme's Amputation.

Mr. Jones describes a modification of Syme's amputation which he has practiced in four cases with success, in the *Brit. Med. Jour.*, May 10, 1884. It consisted in leaving untouched the cartilage capping the lower extremity of the tibia. After disarticulation of the foot, the malleoli alone were removed. By adopting this mode of operating, the amount of exposed cancellous tissue was materially diminished, and so also were the risks of suppurative osteomyelitis. The anterior incision should be made slightly convex, with the convexity directed forwards; otherwise the operator might find some difficulty in approximating the edges without undue tension. The stumps were of a good shape, and readily bore pressure.

Bromide of Ammonium in Puerperal Mania.

In the *Southern Practitioner* for June, 1884, Dr. J. B. Jackson reports a case of puerperal mania coming on the fifth day after delivery, wherein chloral and bromidia signally failed. He then prescribed the following:

℞. Ammonii bromid, ℥ j.
Water, ℥ iij.

Sig.—One teaspoonful every three hours in day time.

Ordered treatment continued, and when he called next day she was combing her hair. She laughed and said, "Doctor, I am not poisoned, I am well." She recovered without another untoward symptom. In these cases where we have a feeble circulation, he is satisfied that we will find ammonia bromid. second to nothing. These cases are rare in country practice, but when they do occur, they require prompt attention, as the friends become very anxious.

Subnitrate of Bismuth as a Surgical Dressing.

After extolling its merits and relating cases in the *San Francisco Western Lancet*, February, 1884, Dr. J. F. Morse concludes by saying that it is an excellent surgical dressing. He calls attention to the fact that the subnitrate of bismuth produces a peculiar change in the difference of the granulations filling a wound. If they are pale and flabby, they at first become black, and then firm, and assume a purplish hue, and if they are bright red they change to the same purple color. The secretions which escape from a wound, providing the wound is a fresh one, are also changed to a jet black hue during a short interval.

Ferric Chloride Reaction in Urine.

The addition of ferric chloride to urine may teach us: If a green discoloration ensues, it denotes the presence of bile, and also proves that the urine is rich in Indican. If an intensely red discoloration takes place in diabetic urine, it seems to indicate that fatal coma is approaching. The same reaction frequently happens in cases of cancer of the bowels, and in one case, where besides pain (which could not be definitely located) in the abdomen and gradual emaciation, no other symptom indicated the existence of a grave disease, the reaction mentioned enabled the physician to make the diagnosis of cancer of the bowel, and the post-mortem examination is said to have verified the diagnosis. In perityphlitis, the reaction ensued.

Probably an Accident.

We find in the *Rheingauer Burgerfreund* the following two advertisements, printed in the same manner as we bring them:

"1. *Special Notice.*—I may be daily consulted professionally from 3½ to 5 p. m. in my private sanitary institution X. to Y. on the Rhine. Dr. F. R., practical physician."

"2. *The respected public* is hereby informed that I have settled down in X. as barber and surgeon. My residence is———. With high regards, I. N. authorized surgeon II. Cl."

In some parts of Germany there still exists surgeons II. Cl. These are barbers who have the right of cupping, leeching, pulling of teeth, venesection, and other minor surgery. As the new law does not recognize these hermaphrodites, they will soon disappear.

The Urine in Strangulated Hernia.

The Paris correspondent of the *Brit. Med. Jour.*, (May 10, 1884,) says that Dr. Englisch, of Vienna, on examining the urine of patients under treatment for strangulated hernia, has ascertained that it always presents albumen in proportion to the duration of the strangulation. If surgical means be not adopted, the albuminuria continues until the death of the patient. The quantity of albumen is not affected either by the date of the hernia, the size of the sac, the frequency of anterior strangulations, nor by a febrile condition. When there is simply protrusion of the omentum, albumen is absent. Professor Nothnagel attributes this albuminuria to diminished intravascular pressure, resulting from the presence of a strangulated hernia.

Liquor Arsenicalis in Nævus.

Dr. John Blair reports a case in one of our foreign exchanges, where, after seven weeks use locally of this drug, the patient was entirely cured, and that without appearing to suffer any pain, except for a short time when the nævus was ulcerating. He had to stop the application on two different occasions, owing to severe gastric disturbance, which he attributed to the absorption of arsenious acid, and which ceased after a rest of two or three days.

Correspondence.

The Title "Eclectic;" Conception without Intromission.

Eds. Med. and Surg. Reporter:—

I see, in the number for May 31, 1884, of Medical and Surgical Reporter, in your notice of Dr. Hamilton's "Conversations on the Subject of Medical Ethics," you say that Dr. H. is in error as to the title "Eclectic," adopted by the medical school of that name. They adopted the title for the reason given by Dr. H.—as I know of my own knowledge. I had it from Dr. T. V. Morrow, who was at the head of the movement when it was adopted, and from several others who were with him in it. I attended lectures there in 1846–7.

I have seen three letters in the Medical and Surgical Reporter, reporting cases of pregnancy without intromission. When reading medicine forty-two or forty-three years ago, I saw the statement "That John Hunter said that a young woman lying on the dissecting-table was pregnant. He judged by areola around nipple. On examining pudenda, a hymen was found with very small opening. Hunter insisted he was right, and on opening the uterus a fœtus was found." I believe the book I read it in was "Dewees' Midwifery." In 1845 or 1846 a girl came to our office and told me she "had taken cold and stopped her courses." I questioned her some, and then said I thought she was pregnant. She requested me to examine her *then*, as she was sure it could not be: she had not had intercourse. I found a hymen with an orifice about ⅜ inch in size. Still I said she was pregnant, and told her how she got it. She had thought intromission necessary, or no danger. I explained to her and the young man that it had been thrown in by force of the discharge. They married in two days, and all went well; the baby came in 6½ months, fully developed.

Davenport, Iowa. W. H. Davis, M. D.

High Operation in Senile Gangrene.

Eds. Med. and Surg. Reporter:—

In a recent number of the Reporter I saw an article on the subject of amputation in senile gangrene, recommending the high operation in such cases. This brings to mind a case which I treated in the summer of 1881. Inasmuch as the profession is not agreeed upon the time and manner of operative interference in such cases (some recommending no operation until a line of demarca-

tion is set up, and others being very uncertain in their teachings), and inasmuch as experience and observation are often necessary to a definite line of treatment, I submit a report of the following case for publication:

On June 21, 1881, I was called to see Mr. A., aged about 70 years, on account of dry gangrene of two toes (first and second) of right foot. He lived in an adjoining county, and was under the professional care of Dr. James Hoffman.

His general condition appeared pretty good for one of his age. We agreed to amputate the foot, and accordingly performed Chopart's operation, the patient being under chloroform. He did very well for a while, and hopes were entertained of a speedy recovery. But about July 1, gangrene attacked the stump, and on July 5, in consultation with Dr. Hoffman, we agreed to amputate above the *knee*, and did so at once. The patient was not in as good a condition as at the time of the other operation, but bore the operation well, being anæsthetized. On examination, the arteries in the flaps presented a very peculiar appearance, being largely occupied with atheromatous deposits. They were studded with hard, chalky or lime deposits, and were so stiff that the larger ones gaped wide open, with no disposition to collapse, and the smaller ones appeared to the touch like so many hard sticks all through the flaps. These deposits were visible and tangible in the larger arteries in the shape of hard mounds. There was no appearance of any line of demarcation in this case at any time, though the toes had been affected for several weeks before the first operation; and I am of the opinion that if we had waited for such line the patient would have died.

After this last operation the patient recovered promptly, and had no return of gangrene, and lived in fair health and comfort until a few weeks ago, when he died, but I know not from what cause.

I forgot to say that Dr. Wm. L. Moody (now deceased) was present, and assisted in one of these operations. N. T. Dulaney, M. D.

Blountville, Tenn., April 24, 1884.

Herpes Preputialis.

Eds. Med. and Surg. Reporter:—

Mc.'s case (page 732, June 7, 1884,) is, in all probability, one of herpes preputialis, and is, when it occurs after coition, excited by contact with an irritating discharge from the vagina of the female with whom he has sexual intercourse; and if a vaginal examination be made, the parts will be found hot, tender, and covered with a secretion unhealthy both in odor and appearance. Therefore, it is very likely that both parties need medical treatment of a local and general character. Supposing Mc.'s patient to be a married man, his wife should at once receive attention. She should be ordered:

℞.	Iodide of potassium,	ʒj.	
	Bromide of potassium,	ʒij.	
	Pulv. chlorate of potash,	ʒj.	
	Simple syrup,	ʒij.	
	Aqua distil.,	ʒiv.	M.

Shake well and take a tablespoonful before each meal and at bed-time, with a five-grain blue pill night and morning. Locally she should use:

℞.	Plumbi acetas,		
	Zinci sulphas,	āā ʒj.	
	Aqua distil.,	Oj.	
	Tinct. opii,	ʒij.	M.

For an injection a No. 2 hard rubber female syringeful of this injection should be injected into the vagina three times a day. This treatment should be continued until all heat, tenderness, and discharge have disappeared frpm the vagina, being careful to omit the blue mass as soon as the gums are touched. In the meantime, the husband should be kept under the influence of protoiodide of mercury, or iodide of potassium and blue pill, for two or three months at a time, omitting the mercurial as soon as the slightest tenderness of gums appears, and be directed to wash his penis well with cold water after each act of coition, and to powder it immediately with finely powdered oxide of zinc. Should he have diseased his wife, as I am supposing, sexual intercourse with her ought to be firmly proscribed until both are well. J. B. Johnson, M. D.

Washington City, D. C.

A Valuable Mercurial Powder.

Eds. Med. and Surg. Reporter:

More than thirty years ago I met with several cases of typhoid fever, wherein intestinal hemorrhage occurred about the eighth to twelfth day, which was easily arrested, but was followed by a low fever, with a red, dry tongue, with other symptoms of disease of the mucous membrane of the duodenum and ilium. I wanted a very mild mercurial, and prepared a powder by rubbing blue mass with pulverized white sugar, small doses of which I found produced a very satisfactory effect. I afterward made a preparation by rubbing mercury with sugar of milk—1 part of mercury to 9 of sugar of milk by weight—and have used the same preparation from that time to the present, discarding calomel and blue mass with great satisfaction. My druggist constantly keeps a supply of the powder on hand.

I find in Ringer's Therapeutics he refers frequently to what he calls the *grey powder*, but for which he gives no formula nor mode of preparation, but which I suppose to be the same as my mercurial powder, which is a bluish-grey powder. I regard it a very valuable preparation of mercury, from the use of which I have never known a case of salivation to follow. Combined with pulv. ipecac, five parts of the mercurial powder to one of the ipecac by weight, I have found it the most valuable combination in fever with intestinal irritation, or in dysentery, I have yet met with.

The mercury must be rubbed with the sugar of milk, in a mortar, not only until the globules disappear, but until the color of the powder assumes a decided blue tinge, and the powder mixed with ipecac. I regard a most thorough trituration as a condition necessary to the proper preparation of the medicine.

Although I have constantly used this preparation of mercury for over thirty years, and regard it the most valuable preparation of mercury we possess, I have never seen the form or manner of preparation in any medical work, or work on therapeutics or materia medica.

It is specially valuable in low forms of fever

with dry, red tongue, or a dry, furred tongue of a brown or yellow color. Its effect seems to be to allay irritation of the mucous membrane and also to stimulate and loosen the secretions of the stomach and liver.

The mercurial and ipecac combination with one-half to one-drop doses of tinct. aconite diluted in water, I find the most reliable remedy yet met with to meet the indications found in catarrhal fever, so prevalent during the past winter and spring in both children and adults, in one-half to three or four grain doses. The mercurial powder alone, in doses varying from two to eight or ten grains, I find the proper dose.

Mt. Pleasant, Iowa. W. Bird, M. D.

Thompsonianism: Lobelia Inflata: Indian Tobacco.

Eds. Med. and Surg. Reporter:—

I have known this thing almost from its birth. Some 50 years ago it sprung up in this vicinity like a huge toadstool in a foggy night. It prevailed mightily, but like its prototype, withered before the rising sun. Its success proved suicidal. I could give you the story, both sad and funny, but *it isn't worth while.*

The following paragraph from a review of "The New System," published at that time, may afford information to younger readers:

"The first thing that an inquirer into the 'New System' learns is that it is patent, and that before he can be initiated into its mysteries, he must pay $20 for the book that contains them. But if he should chance to be a practicing physician, he must pay $500 for the same privilege. $20 is the price of a family right; $500 the price for a right to practice it as a profession."

To the uninitiated, the price may seem exorbitant for a duodecimo volume of 300 pages, gotten up, too, in the coarsest manner. But, on opening the book, he is met by a formal agreement between the author and himself, "made in the spirit of mutual interest and honor," to give, whenever applied to, any information that shall be necessary to give a complete "understanding of the system, and imposing upon the latter an obligation of profound secrecy, except to the initiated." The purchaser has, however, by right of purchase, obtained admission into "The Friendly Botanical Medical Society," with all its blushing honors; and is, moreover, entitled to the privilege of a "free intercourse with the members, for information and assistance."

The common name of lobelia inflata, *Indian tobacco*, is descriptive of its near affinity to nicotiana, both therapeutical and toxical. It is, no doubt, an active emetic, though in my hands it has not been reliable, or specially effective. In throat affections, diphtheria, etc., its toxæmic effects may be useful.

I have said that the success of the system was suicidal. I could relate a number of their disastrous cases.

A healthy young man, in carrying a sick wife to her bed in the evening, caused an inguinal hernia. An irregular doctor succeeded in reducing it the next evening; and strangely enough, without any occasion, directed lobelia to be given every hour or two through the night. It caused much sickness, without vomiting. Before the morning he had settled down in an arm-chair, in an unconscious state, from which he could not be roused; and I was called, only to find that he had been dead near half an hour. His breathing had gradually become shorter; his skin cold and clammy. Lobelia narcotism.

R. L., of an intelligent and respectable family, who had a "right," felt unwell in the morning, and took lobelia. It failed to respond, and was repeated, according to rule, until in the night, when, becoming alarmed, they went for their confidential adviser. He directed its continuance, perhaps in larger doses. Soon the narcotism increased, and she manifested symptoms (probably spasmodic) which he pronounced to be the "crisis," assured them that all would now be right, and left her to return home. It was the crisis, for she died, two hours after, of lobelia narcotism.

Previous to this sad occurrence, I had conversed earnestly with the father relative to the narcotic poisons, and their toxic effect, which he seemed to fully comprehend. Subsequently, he acknowledged that she had died with the symptoms I had described, and that the lobelia was probably the cause of her death. E. Michener, M. D.

Toughkenamon, Pa.

News and Miscellany.

American Public Health Association.

The twelfth annual session of the Association will be held October 14–17, 1884, at St. Louis, Missouri, the following topics will be considered:

1. Hygiene of the Habitations of the Poor.
2. Hygiene of Occupations.
3. School Hygiene.
4. Adulteration of Food.
5. Water Pollution.
6. Disposal of Sewerage by Irrigation or Chemical Action.
7. The Observable Effect upon the Public Health of Official Sanitary Supervision.
8. The Work of Municipal and State Boards of Health.

Persons intending to present papers on any of these subjects are requested to notify the secretary at once, and to furnish him with a condensed abstract of the same not later than September 1. Members desiring to participate in the discussion of these papers are also requested to inform the secretary.

It is requested that the complete papers shall be in the hands of the secretary at least three days prior to the meeting, as all papers must be examined by a committee before being read. They may be sent by mail or express to the secretary at his office prior to the 1st of October, after which date to his address at St. Louis, Mo., care of Dr. Jos. Speigelhalter.

Active and associate members have equal rights in the presentation and discussion of papers.

Extensive preparations are now under way for making this the largest meeting that the Association has ever held and the committee urge the attendance and coöperation of persons in all trades and professions interested in the advance-

ment of public health and general sanitary science.

A circular, giving full and concise information regarding local matters, programme, transportation, etc., will be issued in due season before the meeting.

All inquiries of a local character should be addressed to Dr. Jos. Speigelhalter, Chairman of Committee of Arrangements, St. Louis, Mo.

IRVING A. WATSON, Secretary.

Ohio State Medical Society.

At the thirty-ninth annual meeting held in Columbus, June 10, 11 and 12, the following papers were read: "Tuberculosis," by Dr. Kinsman. "Impurities in Drinking Water," by Dr. W. J. Scott. "The Necessity for the Radical Operation in Empyema," by Dr. S. F. Forbes. "The Pupils as a Factor in Diagnosis and Etiology," by Dr. H. P. Allen. "Irritation of the Prostate," by Dr. R. Harvey Reed. "Treatment of Varicose Veins," by Dr. J. W. Craig. "Milk Sickness," by Dr. W. M. Beach. "Sanguineous Cysts of the Neck," by Dr. Joseph Ransohoff. "Historical and Critical Notes on the Management of the Third Stage of Labor," by Dr. Reeve. "The Remote Effects of Congenital Phimosis," by Dr. W. J. Conklin. "Foreign Bodies in the Urethra," by Dr. N. P. Dandridge. "Diseases of the Female Urethra," by Dr. C. A. L. Reed. "Restoring the Ruptured Perineum," by Dr. H. Z. Gill. "The Use of Boroglyceride in the Treatment of Suppurative Eye and Ear Diseases," by Dr. D. W. Greene.

Officers for the ensuing year:

President—J. C. Reeve, M. D., of Dayton.

Vice-Presidents.—E. B. Pratt, M. D., of Mt. Sterling; B. W. Davis, M. D., of Marion; C. R. Merriman, M. D., and J. F. Baldwin, M. D., of Columbus.

Secretary—G. A. Collamore, M. D., of Toledo.

Assistant Secretary—C. E. Brush, M. D., of Zanesville.

Treasurer—T. W. Jones, M. D., of Columbus.

The Hippocratic Oath.

Having received several requests so to do, we take pleasure in reproducing the famous Hippocratic Oath:

"I swear by Apollo, the physician, by Æsculapius, by Hygeia and Panacea, and by all the gods and goddesses, that, to the best of my power and judgment, I will faithfully observe this oath and obligation. The master who has instructed me in the art I will esteem as my parents, and supply, as occasion may require, with the comforts and necessaries of life. His children I will regard as my own brothers, and if they desire to learn I will instruct them in the same art without any reward or obligation. The precepts, the explanations, and whatever else belongs to the art I will communicate to my own children, to the children of my master, to such other pupils as have subscribed the physician's oath, and to no other persons. My patients shall be treated by me to the best of my power and judgment, in the most salutary manner, without any injury or violence; neither will I be prevailed upon by another to administer pernicious physic, or be the author of such advice, nor will I recommend to women a pessary to produce abortion, but will live and practice chastely and religiously. Cutting for the stone I will not meddle with, but will leave it to the operators in that way. Whatever house I am sent for to, I will always make the patient's good my principal aim, avoiding, as much as possible, all voluntary injury and corruption, especially all venereal matters, whether among women or men, bond or free. And whatever I see or hear, in the course of a case or otherwise, relating to the private affairs of life, nobody shall ever know it if it ought to remain a secret. May I be prosperous in life and business, and forever honored and esteemed by all men, as I observe and not confound this solemn oath; and may the reverse of all this be my portion if I violate it and forswear myself."

New Hampshire Medical Society.

At the ninety-fourth annual meeting held in Concord, June 17 and 18, the following papers were read: "The Importance and Welfare of Medical Associations, Especially the New Hampshire Medical Society," by Dr. J. W. Parsons. "An Inquiry into the Causes of Insanity, with Especial Reference to Prevention and Treatment," by Dr. C. P. Bancroft. "Aids in Obstetrics," by J. G. Anthoine. "The Report on Surgery," by Dr. Edward O. Otis. "Surgical Cleanliness," by Dr. Charles R. Walker. "Diseases of the Eye," by Dr. S. M. Dinsmoor. "Treatment of Phthisis," by Dr. S. C. Morrill. "Respiratory Irrigation in the Treatment of Empyema," by Dr. E. S. Berry. "Mother's Marks," by Dr. M. C. Lathrop. "Report on Gynecology," by Dr. Ezra Mitchell. "Report on Obstetrics," by Dr. Mary S. Danforth. "Laceration of the Perineum," by Dr. Perkins.

Officers for ensuing year:

President—Dr. John Wheeler.

Vice-President—Dr. George A. Crosby.

Secretary—Dr. G. P. Conn.

Treasurer—Dr. D. S. Adams.

Executive Committee—Drs. Charles R. Walker, Geo. D. Towne, and John R. Kimball.

A Good Opening.

The *Allgemeine Wiener Medicinische Zeitung*, of March 11, contains the following advertisement in prominent type:

"A young unmarried doctor of medicine, of the Jewish persuasion, has the opportunity, by marriage, and the succession to a lucrative dental practice, of insuring a very agreeable existence. The practice can be proved to be worth 10,000 florins per annum. The young lady in question is the daughter of highly respectable parents, seventeen years of age, handsome, well brought up, and equally well educated. Her father is desirous of retiring from the business, and will make over to a young doctor of medicine, without compensation, his dental practice, and his excellent dwelling house, with all the material, dental instruments and apparatus of the value of from 8,000 to 10,000 florins. A knowledge of the dental art is not at first requisite, as, under the tutelage of the present professor, this can be acquired in a few months."

Applicants are referred for further information to the editor of the journal.

Lady Practitioners in Ancient Athens.

From a foreign exchange we learn that one of the very first of these was Agnodice, who, while yet a girl, was passionately fond of the medical art, and with a view to practice disguised herself in male attire, and attended the prelections of Hierophilus. When duly qualified, and still retaining man's clothing, she visited many patients, particularly females. The regular practitioners, who found themselves losing their *clientèle*, among women especially, cited her to appear before the Court of the Areopagus, where she was tried, and on the point of being condemned. At this juncture her female patients came forward, and gave evidence how much they, and through them the State, owed to her practice. The Athenians thereupon changed their law, and admitted free-born females to become medical practitioners.

Antimony in Clothing.

The *Centralblatt für Textil Industrie* records the fact that antimony is to be found in cotton yarn which has been dyed with aniline colors, and remarks that unless great care has been taken in the cleansing of the yarn, it is possible for such a quantity to remain as to be injurious to the skin. Experiments made on different classes of yarn produced results varying according to the nature of the dyeing substance. The samples in which hot water acted as a dissolvent showed only a small proportion of antimony, the highest proportion found being 0.014 per cent. The proportions of antimony which were soluble in muriatic acid varied from 0.036 to 0.31 per cent. of the weight of the yarn. Of course, practically speaking, only the portion soluble in water comes under consideration, but as a pair of long cotton stockings weighs about two to two and a half ounces, the antimony would represent an appreciable, though minute, quantity, the effect of which is a question, it is remarked, for medical experts to decide.

Fatal Poisoning from Cake.

The *Louisville Med. News* tells us that a fatal poisoning, supposed to be caused by a specimen of cream sponge, occurred in Louisville recently. A father and his two little daughters felt seriously ill after eating the cake, and one of the girls died. The cake, bought at a neighboring shop, was made by one of the oldest and best confectioners in the city. He claims that portions of the same material used in making this sponge were used in some of his other cakes, and that none of his customers have been made sick by them. The case is still a mystery which, it is hoped, the chemist will be able to unravel.

New Disinfection Furnaces at Paris.

Mortuary depositories have been ordered to be erected in the Paris cemeteries, and these depots, of which there is one at Père la Chaise, are to be supplied with disinfecting apparatus, which will not only be employed in the case of death, but will be open to the public for the disinfection of the clothes and bedding of the sick. The Assistance Publique now possesses ten gas furnaces, three at the St. Louis, and one each at seven other hospitals. These establishments, together with ambulances for the conveyance of patients suffering from contagious diseases, the Parisian population owe to the exertions of several hygienists, as MM. Pasteur, Colin, Vallin, Vidal, etc.

Homeopathy.

Speaking of this schism, Dr. Wythe, in the *Pacific M. and S. Jour.*, March, 1884, says:

"Yet we are asked to regard such dreamers as our equals in science, and a bill is now even in the Senate of the United States to enable them to practice in our army and navy with full rank and pay. Such a bill should never pass until we are fools enough to believe that our cannon-balls should be reduced to homeopathic pellets, and the ten-millionth of a grain of gunpowder will do more execution than a full-sized cartridge."

Items.

—In 1878 the importation of quinine was 17,549 ounces; in 1883 it was 1,055,764 ounces.

—It is said that the recent flood has improved the health of Cincinnati by cleansing the unhealthy districts.

—Fifty-four amputations in one day are said to have been performed by Von Graefe during his active military service.

—It is stated that more than 1,000,000 persons, or one-quarter of the population of London, are the recipients of gratuitous medical aid.

—A man is reported to have died in Ireland recently from blood-poisoning, caused by a bite inflicted on his face by a man with whom he was fighting.

—The progress of cremation is attested by a project for building a crematory at Bordentown, N. J., the idea being that it will be within easy reach of both New York and Philadelphia.

—For the relief of intense itching, Dr. Startin, in the *Lancet*, recommends sponging the parts once or twice a day with pure rectified spirits containing 1 per cent. of carbolic acid.

—Dr. Lawson Tait, of Birmingham, England, is about to visit this continent for the purpose of giving an address on abdominal surgery before the Canada Medical Association at Montreal, Aug. 25.

—Dr. Posada Arango praises nux vomica, in doses of 10 drops of the tincture three times a day, as a galactagogue. Where there is a complete suppression of milk, strychnia is to be preferred.

—The Senate has passed a bill changing the title of United States surgeons with the rank of colonel to assistant surgeons-general, and of those with the rank of lieutenant-colonel to deputy surgeons-general.

—The contagiousness of consumption has gained substantial recognition in New York, if we may judge from the announcement that certain wards in Charity Hospital are to be set apart for the isolation of consumptives.

—The German Parliament has awarded to the German Cholera Commission the sum of $50,000, *i. e.*, besides their salaries and expenses. Medical science is more acknowledged in other civilized countries than in ours.

—Dr. Robert Koch, the distinguished discoverer of the bacillus of tubercle and of cholera, is described as a man of medium height, thin, grey-haired, with a serious, spiritual countenance. He looks much older than he is—forty-one.

—The ashes of Professor S. D. Gross weighed about seven pounds. They were enclosed in a marble urn about three feet high, unornamented, and without inscription, and placed beside the coffin of his late wife in the family vault at Woodland Cemetery.

—In the *Brit. Med. Jour.*, May 31, 1884, Dr. Albert E. May reports a case of operation for strangulated femoral hernia in a woman eighty-five years of age—recovery; and Dr. Charles J. Marsh a recovery from a similar operation in a woman aged 75.

—According to the *Medical Times and Gazette*, the universities of Prague and Gratz have each established a chair of hygiene, the chair at Prague to be filled by Dr. Soyka, and that at Gratz by Dr. Gruber, both of these gentlemen having been pupils of Pettenkofer's.

—The International Congress of Hygiene meets this year at the Hague, August 21st. Dr. Van Overbeek de Meijer, Professor of Hygiene at Utrecht, is secretary. The Dutch Minister of the Interior is honorary president. Pasteur will be present and read a paper.

—Dr. William Goodell, of Philadelphia, recommends the following prescription in pruritus vulvæ: Carbolic acid, one drachm; morphine sulphate, ten grains; boracic acid, two drachms; vaseline, two ounces. Also, pat the parts with a sponge soaked in boiling-hot water.

—M. Pasteur has been furnished with an opportunity of testing his theories concerning rabies upon a human subject. One of the servants of the Paris and Lyons Railway at Tarascon-sur-Rhone, having been bitten by an undoubtedly mad dog, has just placed himself in the hands of the illustrious savant.

—Dr. Charles D. Homans, of Boston, the newly-elected president of the Massachusetts Medical Society, comes of a rather medical family; that is to say, he is a son of Dr. John Homans, formerly president of the society, a brother of the distinguished surgeon, Dr. John Homans, and the father of a third Dr. John Homans, who is just now in Europe.

—The new salt field in western New York is expected to produce 600,000 bushels of "the finest salt in the world" this year, and expects to double the production next year. A wide belt of country—the extent of which is not yet determined—is underlaid at a depth of from 1200 to 1600 feet, with a deposit of pure rock salt from sixty to ninety feet in thickness.

—An inopportune dislocation of the jaw is one of the topics dealt with by a *feuilletoniste* writing in a recent issue of the *Union Médicale*. It seems that during the performance of a wedding ceremony the bride sneezed so violently as to dislocate her jaw at the critical moment when she should have pronounced the solemn "oui." As she was unable to articulate the word, it was found necessary for the whole party to repair to a surgeon before the ceremony could be completed.

—Sir Joseph Fayrer, who has been investigating snake poisoning, says that to him one of the greatest of mysteries is that a poisonous snake cannot poison one of its species, scarcely its own congeners, and only slightly any venomous snake, but it kills innocent snakes quickly. A vigorous cobra can kill several dogs, or from a dozen to twenty fowls, before its bite becomes impotent, and then the immunity is of brief duration, for the virus is rapidly re-secreted.

—French public prizes are something worth having. The following have just been awarded by the Academy of Sciences: M. Legrand du Saulle, $2,000 for medico-legal studies on epilepsy and the value of wills made by insane or hysterical testators; M. Fauvel, $1,000 for studies on cholera; MM. Strauss, Roux, Nozard, and Huillier, each $2,000 for studying the cholera in Egypt; and MM. Gaston Tissandier, Duroy de Bruignac, and V. Jatin, $600 for advancing the science of aeronautics.

MARRIAGES.

BATES—SMEDBURGH.—In Albany, June 16, 1884, by the Rev. Dr. F. L. Norton, Dean of the Cathedral of All Saints, Dr. Wynkle G. Bates, of Boston, and Elizabeth, younger daughter of N. C. Smedburgh, of Albany.

BEAN—KINGSBURY.—In Lyme, N. H., June 7, 1884, by Rev. E P. Butler, Dr. J. Walter Bean and Ellen S. Kingsbury, both of Lyme.

BEEKMAN—DAWSON.—On Wednesday, June 4, 1884, at the Church of the Ascension, by the Rev. E. Winchester Donald, and Rev. Wm. H. Neilson, of Trenton, New Jersey, Dr. John N. Beekman and Annie L., daughter of the late B. F. Dawson, New York.

CHARLES—ESHLEMAN.—June 5, 1884, at the residence of Jacob Kurtz, near Ephrata, by Rev. S. Schweitzer, Dr. J. Charles, of Lincoln, and Miss Lucinda Eshleman, of Ephrata, Pa.

MARCY—HATHEWAY.—In New York, June 11, 1884, at the Tabernacle Church, Broadway and 34th street, by the Rev. Wm. M. Taylor, Dr. T. Knowlton Marcy and Miss Ellen M. Hatheway, both of New York city.

TALBOT—BRANNAN.—In New York, June 4, 1884, by the Rev. E. W. Donald, Dr. Bower Talbot, of Sutton, Northamptonshire, England, and Alida, daughter of General J. M. Brannan, United States Army.

TODD—TEN BROECK.—At New Brunswick, N. J., June 5, 1884, by the Rev. Dr. Todd, J. C. Todd, M. D., of Tarrytown, N. Y., and Elizabeth Buchanan, daughter of the late R. V. D. Ten Broeck, of New Brunswick.

WHITTAKER—HARRISON.—In Cincinnati, Ohio, on Tuesday, June 3, 1884, at the residence of the bride's mother, by Rev. Dudley W. Rhodes, Dr. Ias. T. Whittaker and Ella M. Harrison.

WILDER—TAYLOR.—In Cincinnati, Ohio, on Tuesday, June 10, 1884, at the residence of the bride's parents, by Rev. Dr. Dickinson, Dr. Wm. H. Wilder, of Walnut Hills, and Miss Ella Taylor, of College Hill.

DEATHS.

ADAMS.—At Liverpool, England, on Thursday, June 19, 1884, John G. Adams, M. D., son of the late John Adams, all of this city.

CHALMERS.—At New York city, June 4, 1884, at his late residence, 25 West Seventeenth street, Thomas C. Chalmers, M. D., in the 74th year of his age.

GREEN.—At Green Hill, Worcester, Mass., Wednesday, May 28, 1884, Dr. Samuel Fiske Green, brother of Andrew H. Green, of this city.

SUTTON.—In New York, on Friday, June 20, 1884, Wm. Sutton, M. D.

VAN WAGNER.—In New York, on Monday, June 9, 1884, James E. Van Wagner, M. D., in the 83d year of his age.

WORTMAN.—In St. Louis, on June 10, 1884, Dr. Wm. S. Wortman, aged 55 years and 4 months.

REFLECTIONS AND SKETCHES OF TOWN AND COUNTRY PRACTICE.

BY GEO. HILL, M. D.,

Of Hughesville, Lycoming county, Pa.

One of your correspondents (Dr. H. Corson) deserves great credit for his incisive grit, in urging the proper use of the lancet, which it seems has become almost obsolete. It is simply incomprehensible that so great a power for relieving pain, relaxing spasm, arresting morbid action, and oftentimes aborting disease, should have fallen into disuse almost everywhere. Forty-six years of continuous experience has left with me but very few regrets for having bled in mistake, while more are in memory for omission of its early and proper use. But in hundreds of instances has bleeding yielded the writer the consciousness of a sudden relief, as well as a permanent benefit, to his suffering patients. In glancing over my last diary—1884—I count more than a score of venesections. This note is not given to champion any specialty in therapeutics, but merely to prove that *a little bleeding is not a dangerous thing*, even in 1884. The abandonment of this old and sovereign remedy is, perhaps, not so much due to the now defunct Thompsonian *way* of practice, as to the more popular *path* of the homeopath, who has his sugar-coated infinitesimals, backed by a flexible literature and principles which enable him at will to abandon his *tiny mite* for 20 grains of quinine, *pro re nata*—and he too a pronounced non-bleeder, *par excellence*.

A few cases are culled, not because of anything new or specially important, but only as a trifling exhibit of what has been done in the past, is now (to some extent), and ever will be.

1. Mr. A. B——, town, retired farmer, aged sixty-eight years, weight 165 pounds. Called in January 6, 1884, at 10 a. m.; has been bleeding at the nose for thirty hours; his wife thinks he has bled nearly two quarts! pulse jerky, and 80; hands and feet cold; goose skin on arms; dizziness and pain in the forehead. Ordered warm bath with mustard for feet and hands; ice in bladders to the head; ergot and bromide of potassium every two hours. At 2 p. m. still bleeding. Now bled from the arm about one pint, with immediate relief of pain and dizziness, and hemorrhage stopped while binding up the arm. Medicine continued four days; able to be about; dismissed. This man had symptoms threatening apoplexy for two years previous to this hemorrhage, and now, after four months, is better than he has been for years.

2. Mrs. S——, town, second pregnancy, aged twenty-five years. Called in at 4 a. m., January 9, 1884. Ruptured the membranes at 10 a. m.; at 1 p. m. pain harassing and frequent; os hot and rigid; presentation favorable, but no progress; gave one and a half grains of opium, and bled about twenty ounces; pains at once became regular and tolerable, and parts yielded favorably; child born in one hour and twenty minutes. Gave half teaspoonful fluid extract ergot immediately after extrusion, and in ten minutes delivered placenta; future all right.

3. Mrs. J. K——, town, age forty; fifth pregnancy. January 10, 1884, 8 o'clock a. m., had pains all night and day before; waters escaped at

9 a. m.; first presentation, 2 o'clock p. m., no progress; patient fretful and nervous; os unyielding and tender on effort at forcible dilatation. As is common in nervous cases, patient determined *to die* at every throe; gave two grains of opium, and in fifteen minutes bled about one pint. Pains now became more tolerable and not so frequent; womb yielding, with occasional vomiting. Child, a male, born at 5 o'clock a. m. Immediately after extrusion, gave a teaspoonful fluid extract ergot, on account of previous tendency to post-partum hemorrhage. Placenta spontaneously cast off in first after-pain. Case proceeded favorably, and recovered perfectly in the usual time.

4. Mrs. K——, town; age, sixty-five years; weight, about 160 pounds. Called in February 13, 1884. Patient sick three days with chills, fever, pains in chest, right side, temperature, 100⅘°; mucous râles; cough with scant and reddish expectoration.

Diagnosis.—Pneumonia; offered to bleed; refused; ordered blue mass, followed by castor oil; also ammonia acetate and tincture digitalis every two hours after physic.

14th. Worse. *Insisted* on bleeding, and removed eighteen ounces of blood, with immediate relief in breathing. Applied a blister 6x6 over the seat of pain. Medicines continued.

15th. Better and free of pain. Expectoration slightly increased and easier.

17th. Improving rapidly.

20th. Convalescent, and needs no further attention.

5. Mrs. P——, farmer's wife. Called in February 14, 1884. Was taken with tooth-ache, pain in frontal sinus and antrum of Highmore of the left side after exposure, suffering severely, and had been for three days. Ordered rest, foot-bath, mush poultice, with mustard about the face and back of the neck, and saline cathartic.

February 3. Getting worse; bled one pint, with immediate relief of pain; ordered salts and former applications.

5th. Better, and then rapidly recovered by resolution.

6. Mr. I. A——, town; age, thirty-two years; weight, 180 pounds. Called in April 9, 1884. Case, inflammation of frontal sinuses and antrum genæ of the right side, four days' standing; growing worse, pain excruciating. Bled in sitting posture till symptoms of fainting appeared, with immediate relief and permanent good. Revulsive catharsis ordered, kept up with salts and senna for two days; nothing more.

These catarrhal cases are often called sun headache, because always much worse during the day, especially from 8 a. m. to 4 p. m. Quinine in full doses is frequently given with good results, especially after free bleeding, which latter should never be neglected if at all admissible, this being the *only* reliable course to bring about rapid resolution, instead of the worse and almost sure ending, suppuration, of which the sequel is often chronic catarrh.

7. Mrs. R——, three miles out, first pregnancy, age 32, medium in stature, plump and florid. Case, labor. Called April 10, 1884, 8 o'clock a. m. Waters entirely drained off the day before. Vagina close and fleshy. Os hot and irritable, and on contraction hardly admitting the tip of finger. Vaginal temperature 100½°. Nurse reported no sleep during the night before. Pains very frequent and harassing. 12 m.—No improvement, pains exhausting; gave opium gr. ij., and bled about ten ounces. 2 p. m.—Pains at longer intervals, with but little improvement. Diagnosis, forehead front. Now bled twenty ounces. Directly after, the patient having occasion to rise, fainted; was laid upon the couch. Examination revealed general flaccidity, when Dr. G. Wood was called in to administer an anæsthetic, and the patient was with the forceps delivered of a living male weighing nine pounds, and as soon as consciousness returned gave her a teaspoonful of fluid extract of ergot, and in twenty minutes removed the placenta. No unpleasant feature occurred in this case after delivery, and recovery is now complete. How it would have been possible to have avoided laceration of the womb or perineum or both in this case without free venesection, is impossible to conceive. I declare emphatically, the thing could not have been done.

One of your late correspondents attributes the *numerous lacerations* of late years to the injudicious use of ergot as an expulsive, with which I agree, but further he finds frequent use for this drug as an expulsive in what he calls favorable cases. In this I disagree, believing there are no such cases, with only the rarest exceptions, where this remedy might be given as an expulsive. The womb that has been goaded to expulsion by this savage drug where there is the slightest impediment, is in many cases, if not lacerated, rendered atonic and a ruined viscus for life. This I know is no exaggeration, by my own experience and that of others. About the only use, for many years, that I find for ergot in the gravid uterus is in quite small doses, in connection with bleeding, to prevent abortion or premature labor.

8. Sarah D——, aged seven years, seven miles out. Called in at 11 o'clock p. m., April 20, 1884. On entering the room found air loaded with a very strong odor. Tonsils, uvula, and a considerable portion of the roof of the mouth densely coated with a half-dry ash-colored deposit, posterior nares also clogged, as the child was breathing with open mouth. Glands much swollen on both sides of the neck, with some tumefaction also under the chin.

Diagnosis.—Malignant diphtheria; prognosis, death. Gave the child chlorine water, glycerine, and sulpho-carbolate of soda, which soon corrected the horrible odor emitted from her throat.

This is one of the sort of cases in which whisky can be administered in enormous quantities without inebriation. The child swallowed with difficulty, but manifestly without much pain; the absorbents of the stomach in a state of atony; the viscus a mere receptacle. The patient was allowed grog in such quantity as might not be chemically injurious if recovery were possible. The diet, hydrocarbons, as fat, sugar, and starch, and all albuminous and fibrinous diet absolutely forbidden; and not only so in diphtheria, but they should be as surely also in all zymotic diseases. The critic may say this is mere theory:—it is; but what is practice without theory? The physician who prescribes the simplest pellet without theory, is a *professional sinner*.

Child died Monday, 23d, at 5 o'clock a. m. As this case has special interest, the history is here given.

April 13, 1884, the father, mother, and child went nine miles distant on a visit, and remained over night where the disease is prevailing. Sarah slept with a child who had sore throat. She had, in the opinion of the parents, taken cold on the return the next day, as it was cold and rainy; and on Tuesday, April 16th, commenced with chills and sole throat, growing worse until Saturday night, when I was called, and found the case as represented, without hope. One point of interest is, that here is a case of diphtheria fully initiated in but a fraction beyond two days after exposure to the contagion, in a child in the best of health, living in a district where there is not a case within three miles, and never one before in the house.

In a former number of the Med. and Surg. Reporter, I took the ground that this *causus morbi*, when present, may remain dormant for an indefinite period, and even die out of the system, without development, and further that colds in winter favor the development of the disease; and I now add the logical inference that if the soil is in condition and the seed sown, it will sprout immediately.

There are in this family four other children: one girl nine, one eleven, one son fifteen, and an elder sister twenty years old. On my first visit I urged that all of these children be put under vigorous preventive measures forthwith, when the following was written and in a few hours put to use:

℞.	Chloral hydrate,	grs. xc.
	Glycerine,	f.℥iv.
Dissolve, and add,		
	Aqua creasoti, q. s., ad	f.℥viij.
Mix.		

Sig.—Dose, respectively, 1, 1½, 2, and 2 teaspoonfuls in water every four hours day and night, according to the ages.

This combination was chosen at this time on account of its specially antiseptic and rapidly diffusible qualities, and was followed by

℞.	Aqua chlorinæ,	f.℥iij.
	Glycerine,	f.℥ij.
	Aqua creasoti, q. s., ad.,	f.℥viij.
Mix.		

To be taken as above, and to be continued eight or ten days.

On my first visit, April 23, the oldest girl, who had been in constant attendance on Sarah, the deceased, had some inflammation of the throat, with a slight deposit on the left tonsil. The boy had been ploughing and had taken a cold. Upon his right tonsil two small specks of real deposit were seen. The two younger girls have presented no disease at any time, although the youngest one was much of the time in immediate contact with the sick sister. On the 25th everything like diphtheria had disappeared, and yesterday, May 10th, all were well, and from past similar experience I think safe from contagion.

It seems that in chlorine and its compounds, in proper combination with several of the alcohols, lie all our hopes for neutralizing the zymotic poisons as far as yet known; and none of them perhaps is more essential than glycerine—not only as an antiseptic, but on account of its affinity for moisture, is it adapted to enter into the compounds, especially all gargles, thereby facilitating the early sloughing of the deposit.

It is to be hoped that pathology may soon learn a lesson from advanced chemistry in nomenclature, or rather that disease shall be designated, as far as possible, by the lesion instead of a symptom, which latter is ever misleading. It is just as correct to call diphtheria a fever as the *intestinal affection* and succeeding *lesions* which constitute what is falsely called typhoid fever. When

this is done, then it will become clearer why whiskey and spirits of turpentine have long had earnest but perhaps somewhat blind advocates in the latter. It might then also reasonably follow, or occur to the medical mind, that early and thorough antisepsis of the bowels and air passages may not only cure, but actually cut short or even abort this *typhoid inflammation of the bowels.*

A MISTAKE IN DIAGNOSIS: MAMMARY ABSCESS EXTRAORDINARY: DEATH IN NINETIETH YEAR.

BY E. MICHENER, M. D.,

Of Toughkenamon, Pa.

Rachel, the widow of Thomas Hicks, late of London Grove, Chester county, Pa., was born 1789–1–18. Having an ample development of all the tissues, she was a large woman, though not obese; possessed great physical and mental energy, and remarkable endurance. She married late in life, and had one child in her *fortieth* year of like ample dimensions with herself. The labor was natural, but was tedious and severe. It was followed by an equally tedious and severe *phlegmasia dolens.* And this, in turn, resulted in obstinate *ulcers* on the affected limb, causing much suffering in after life.

In 1867–6–19, then in her seventy-eighth year, she had a fall, fracturing the *os femoris* and inflicting other injuries, which, for a time, placed her life in jeopardy.

After her widowhood, she removed to her home with her daughter, *Amy H. Fell*, near New London, where *Dr. Fulton* was the family attendant. To him, to her daughter, and to her step-daughter, *Mary H. Bernard*, near Doe Run, I am indebted for details in her subsequent history.

"As she still complained of those ulcers, which had continued, without particular change, for forty years (near fifty), about a year, perhaps more (it was probably three years) before her death, I commenced the treatment of them, mainly by strapping, and succeeded in healing them."—*Dr. Fulton.*

"I think it was some three years before her death mother had something like *erysipelas* of the ankle. Dr. Fulton attended her. The ulcers did not trouble her much afterward."—*Amy.*

Soon after—1877–10–30—then near the completion of her eighty-eighth year, while on a visit to her step-daughter, she again fell, on a stairs, and was badly hurt. It was, and is generally believed, that the mammary disease was the result of a contusion then received.

"I am not convinced that her breast was hurt then. She did say while in bed that her breast hurt her. There was slight hardness, but no discoloration. After attention, and bathing, she soon ceased to complain of it. I think that it was diseased before the fall."—*Mary.*

"When mother returned home, her head was *affected*, and her hip *very painful* for a long time. As the face and hip on that side were injured, the breast could hardly escape."—*Amy.*

The date of discovery of the tumor, after the fall, is not known. Rachel survived the fall about fifteen months. *Amy* thinks from recollection that the tumor was about six months in maturing, which would allow more than another six months for the *incubatory* period.

"When I first discovered it, the tumor was the size of a hickory nut. She did not complain of it till it had become much larger. It was located near the centre of the breast."—*Amy.*

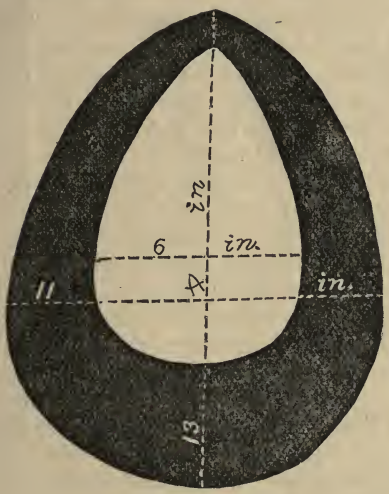
In 1878–10–10, Rachel Hicks and daughter, returning from meeting, paid us a social visit. It had often been told that she had a cancer that was rapidly growing worse; and that any treatment would be useless and inexpedient at her age. This I had accepted as the judgment of Dr. Fulton, but Amy informs me that no other physician has seen the case.

On a careful examination I found the milk gland more than twice the normal size during the nursing period. It was almost of stony *hardness*, with the surface mostly *smooth*, except an inch of its inferior margin that was still soft and quite *natural* to the feel. It moved freely, and bore pressure with scarce any tenderness. The little pain that she felt in it seemed to her to be caused by the weight and dragging of the tumor; with the exception of frequent slight twinges shooting through it. The skin of the breast was perfectly *free, soft, and natural* in color, touch and temperature.

After due consideration of existing symptoms, and the extraordinary history that I have eliminated, I could only follow trail, and call it *a scirrhous degeneration of the mammary gland.* My only suggestion was a belladonna plaster, and an effective suspensory for the breast. Here the matter rested for almost three months. My impression was that she was under medical advisement, and the numerous reports of increased suffering were not of a kind to create any doubt of the correctness of my *diagnosis.*

In 1879–1–29, I made this sufferer a non-professional visit, and judge of my *surprise*, instead of a distinctive *cancer* to find an enormous *mam-*

mary abscess, which, with a milder name, had been no less certainly and rapidly sapping the *life of the patient*. Here was a huge sac of attenuated cutis, resembling a large bladder, distended with fluid, surging back and forth with every motion of the body, and ready to burst at any moment from the weight of its contents. When erect, it appeared as if suspended from a point just below the clavicle. When reclining, it became more oval and depressed. By a cautious manipulation I was able to ascertain the base of attachment, and to measure the vertical and transverse diameter and circumference of the sac.



Measurements.—The white base 6 by 8 inches.

The black overlap varied with position, 13 by 11 inches.

Vertical circumference about 27 inches, including base.

Horizontal circumference about 26 inches, including base.

I learn that several physicians had transiently seen the case since the softening, but for *etiquette* or other reasons, avoided interference. I strongly urged its earliest discharge at whatever hazard. It was accordingly done by Dr. Fulton, who in response writes:

"The amount taken away when first opened, was *two and a half quarts* of dark, offensive, unhealthy pus. The discharge continued till the time of her death. There was no after-adhesion of the skin to the muscular tissue. The gland was not entirely collapsed. She finally sunk, with the appearance of *lung congestion*—whether from absorption of *poison*, or some other influence, was difficult to answer."—*Dr. Fulton.*

"It was opened the 2d of 2d month, 1879, fifteen months after the supposed injury. She held the bowl while it was discharging. It was so great during the night that I had to change all her clothing. But she arose, dressed herself, and with assistance walked down stairs. She grew weaker, but did not seem to suffer much. On the 22d, she grew worse; the breathing became quite difficult, etc., until the 5th of 3d month, 1879."—*Amy.*

She died thirty-three days after the discharge of the abscess, aged ninety years, one month, seventeen days. I can fully adopt the following response as my own:

"The question has frequently arisen in my mind, whether it is possible that the *drying up* of discharge, *so long continued*, in a person of her age, had any influence on the after results."—*Dr. Fulton.*

The sad mistake in the *diagnosis* of this interesting case is greatly to be regretted, as it caused much unwonted suffering; but I have yet to learn how any one could have decided differently. Nor is it strange that she, and a numerous circle of intelligent friends, should have accepted my diagnosis, and concluded that active treatment would be useless and inexpedient. But it is *very remarkable*, that when the tumor *broke down*, there should have been no one found to notice and suggest the character of the change that had taken place. I have placed the whole history of the case on record, as a *beacon light* for others to walk by. While I deprecate *hasty censure*, I cordially invite *friendly criticism.*

DEATH AMONG THE MAGNATES.

BY C. C. VANDERBECK, M. D., PH. D.,
Of Philadelphia.

There seems to be something enticing in the inquisitiveness one has about the manner of death of a great man or woman. In fact the curiousness is not restricted concerning magnates, but we all find it a foremost question in our mind when the death of a friend or a neighbor is announced, "Of what did he die?" For twelve years it has been my constant habit of reading, like Madame de Stael, with pen in hand, taking copious notes, saving striking thoughts, and pretty couplets, as well as important points in science, art, literature, and history. From this material, now grown into a half-dozen good-sized volumes, preserved by being well bound, the material of this article has been garnered. To some of our profession who can hold for a moment from the eager grasp after

the practical, and enjoy general medical literature, I commend my labor.

Death does not approach the rich and the great any more than it does the poor and obscure, with dignity and courtly bearing. It is surprising how trivial has been the agent ofttimes, such as a mosquito or bee sting, or a spider bite. Pope Adrian lost his life by the sting of a gnat; Anacreon, the famous Greek poet, by the seed of a grape; and Emperor Charles the Sixth by a mushroom. I do not attempt to make an exhaustive list of the subject in question; doubtless many of my readers can readily add other examples, from whom it will please me to hear.

Apoplexy.—This disease has caused the death of many noted men, among whom are the following: Leonard Euler, while playing with one of his grandchildren, at the tea-table, was seized with an apoplectic fit, and died in a few hours. Dickens, and Thackeray, who was cut off in his fifty-second year, dying alone and unseen in his chamber, before daybreak on the morning of December 24, 1863. His brain weighed 58½ ounces. Napoleon I., and Charles the Second, of England, who, in the midst of a life of vicious indulgence, was attacked by apoplexy, and died after a few days' illness, February 6, 1685, being fifty-five years old. Morton, one of the three disputed discoverers of modern anæsthesia, died from a stroke of apoplexy. Dr. Wm. Hunter, Napoleon III. (embolism), Thiers, Wickliffe, Peyton Randolph, first President of our Republic. J. Q. Adams was stricken down, if I mistake not, in the House of Congress. Louis XI. and Charles VIII. of France. George I. is said to have died of apoplexy, though others say it was of drunkenness, politely called apoplexy by his physicians. Henry VI. is reported to have died of apoplexy, though there is some doubt of this. Vice-President Wilson had three different strokes of palsy, the third and fatal one occurring two years after the first attack. Ex-President Johnson also died of apoplexy. Trajan died in the second attack. Verus, the Roman, also died of this disease.

Angina Pectoris.—Rev. George Junkin, of Lafayette College renown, died of this painful malady, as did also the late Rev. Dr. Bedle, of Philadelphia; and likewise Sir Charles Bell. This great physiologist awakened with a frightful spasm of angina, asked to be supported, and immediately expired, June 12, 1842.

Small-pox.—Queen Mary of England, Pomfret and Louis XV. of France, are recorded as dying of this horrid disease.

Fevers.—Robert the Pious, on returning from a pilgrimage to the chief sanctuaries of France, was attacked by a fever—marsh fever, probably—and shortly died. Louis VIII., putrid fever. Mercedes, Queen of Spain, gastric fever. Alexander the Great died of malarial fever, as did also Lord Byron and Oliver Cromwell. Jeremy Taylor died of some fever. Francis I. of France, "long consumed with a slow fever." Otho III. of Germany of a spotted fever (perhaps poisoned). Constantine died of ague; also Marcus Aurelius.

Lung and Heart Affections.—John Keats, Edward VI., and Laennec, were destroyed by phthisis pulmonalis. John Bunyan died in consequence of a cold caught in a journey undertaken by him in inclement weather, with the object of reconciling a father and a son. Charles Montague, inflammation of the lungs; Whitefield, asthma. The cause of our Washington's death was œdema of the glottis. The late Prof. Biddle died from congestion of the lungs, joined probably with pleurisy. Prof. Dunglison, of heart disease.

Diseases of the Abdomen.—Augustus Cæsar perished from effects of an exhaustive diarrhœa, acting on an old and enfeebled frame. Gray, of gout of the stomach; Livingston, dysentery; Pepin of France, dropsy; Dr. Adam Clarke, cholera; John Racine, abscess of the liver; Caroline of Brunswick, wife of George IV., fell a victim to strangulated hernia (umbilical); Louisa, daughter of George II., when Queen of Denmark, died of an operation for hernia. Queen Caroline, her mother, also died of hernia, after an operation by the celebrated Raub.

Dr. J. Addison Alexander, and James W. Alexander, both of diabetes.

Prof. Henry, of the Smithsonian Institute, acute Bright's disease.

Injuries.—Sir Humphrey Davy died from the effects of an injury to one of his elbows. Louis the Stranger, from a fall from a horse. The Queen of Philip died, also, from the effects of a fall from a horse. Philip IV., while hunting, his horse fell with him and hurt him so badly that he died shortly afterward. Henry II. died from the effects of a lance-wound over the eye, surviving the accident eleven days. Louis VI. lost his eldest son, a promising youth, crowned but two years before, by a fall from his horse. The streets of Paris then were narrow, full of dirt, and pigs were allowed to range about in them. One of these pigs ran against the horse which the prince was driving, and caused him to fall, and the rider was so severely hurt as only to survive a few hours. On this occasion, an order was issued declaring that no pigs should be in future suffered in the streets

Miscellaneous.—Robert Duke, starvation. Augustus II., gangrene of an old wound. Camillus. Louis IX., Thibaud, king of Navarre, Alphonso, the King's uncle, and his wife, Countess of Provence, all perished from the plague. Chaucer, old age. Dr. William Hunter was subject to gout, but during one of these attacks he was paralyzed (as mentioned above), and shortly died. Gray died of gout of the stomach. Burns shortened his days by his excesses. Thomas Olney perhaps choked to death. It is said that when almost starved, the poet received a guinea from a friend, on which he rushed off to a baker-shop, bought a roll, and was choked while ravenously swallowing the first mouthful. Louis X. drank freely of cold water after heating himself with playing tennis, and then sat down to rest in a damp grotto. He was seized soon afterward with a sudden chill, and died the next day. Charles VII. (France) starved himself for fear of prison. Francis II., of France, abscess in the head. Charles the Bold, perhaps poisoned by his Jewish physician. Charlemagne is said to have enjoyed excellent health till just before his death. His last words were: "Into thy hands I commend my spirit." Boadicea, of early English fame, poisoned herself. Edmund, killed by a robber. Richard III., poisoned by his brother, Duke of Normandy. Brunhild and Fredegund, wives of two of the youngest sons of Clotaire, struggled one with the other for many years, and deluged the royal houses with blood. Brunhild finally fell into the hands of Clotaire II., who, after parading her on the back of a camel through his camp, tied the miserable woman to the tail of a wild horse, which dragged her over the rough ground until life was extinct. Henry I., of England, died from a surfeit of lampreys, as he was preparing to leave Normandy to repress an uprising of the Welsh. President Taylor died from the effects of over-exertion in celebrating a 4th of July. Prince William, of England, and Shelley, were drowned. Thomas Chatterton and the wife of Shelley committed suicide. Tarquinius Priscus, fifth king of Rome, noted for the building of the Circus Maximus and the great sewers at Rome, was assassinated.

—It is not often that things are put so plainly as this. In the monthly report of the Cathcart Parochial Board we read: "The inspector then proceeded to read the medical officer's report for the month of March. There were, he said, 'nineteen cases on the roll. The doctor had cured five and killed one, leaving only thirteen on the roll.' He meant to say one had died."

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM GOODELL, M. D.,

Professor of Gynæcology in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M. D.

Fibroid Tumors—Oophorectomy as a Remedy for ~~Fibroid Tumors~~—Dysmenorrhœa—~~Forcible~~ Dilatation.

GENTLEMEN: The first case is one which comes for diagnosis. The patient is a colored woman, 45 years of age, who has been married sixteen years, and had seven children, the youngest of which is five years old. She has not seen the menses for over one month. Previous to this they had been coming every two weeks, and were profuse.

If she were an unmarried woman, or married and sterile, I should say that she either had a fibroid tumor or a polypus. But as she is a married woman and has children, then I would say, if she were white, that most likely she had carcinoma. On the other hand, she is a colored woman, and I have never yet seen carcinoma of the neck of the womb in a colored woman. We therefore come to the conclusion that she has some growth which causes the bleeding. ~~Let me go over this again, for it is important. We have a colored woman, aged 45 years, who has been married sixteen years, and had seven children, who has been having her periods every two weeks, and been losing too much. If this were the history of a white woman, I should say that carcinoma of the cervix would probably be found. She is a colored woman, and as I have never seen carcinoma of the neck of the womb in a colored woman, I lay that aside, and we conclude that the bleeding is due to either a fibroid tumor or a polypus.~~ The diagnosis lies between the rare disease of cancer and fibroid tumor. It is true that the bleeding might be due to fungous vegetations, but usually these do not cause bleeding every two weeks. They produce menorrhagia, with a profuse leucorrhœa between the periods. It might be a malignant growth within the cavity of the womb, but this is rare.

We shall now make the vaginal examination. The womb is decidedly larger than it should be, and on its posterior surface I feel a number of disseminated nodules. This is evidently a case of multiple fibroids. I had expected to find a tumor of some magnitude. The sound gives a measurement of 3.5 inches. I can feel the left ovary, which is hard, enlarged, roughened, and hardened. This is interstitial or parenchymatous degeneration, the result of ovaritis, and is not uncommon. I have never seen but one ovarian tumor in a colored woman, and that was in a mulatto.

I can touch without much difficulty the promontory of the sacrum. She states that all the labors were hard, but that instruments were only used in the next to the last labor, and that all her children were very large. I can trace the sacrum all the way from the coccyx to the promontory. When you can touch the promontory of the sacrum

with the finger, you may be sure that the pelvis is contracted. The promontory can be reached more readily in those cases in which the sphincter perineum is relaxed or torn. In this case the perineum is torn down to the sphincter.

One word in reference to the weight of children. Never accept the statements made by mothers in regard to the weight of their children, for mothers take a pride in giving birth to large children. The babies are often weighed with the clothing on, and no allowance is made for this, or the weight is simply guessed at. You will be told of children weighing fifteen and eighteen pounds. The largest baby I ever saw weighed a few ounces over eleven pounds. That was a very difficult labor. The plan which is adopted at the Preston Retreat enables us to obtain the exact weight. As soon as the baby is born it is placed in the receiving blanket, which consists of a piece of flannel, the exact weight of which is known. The child is then weighed and the weight of the blanket subtracted. When mothers tell me they have had children which weighed thirteen or fourteen pounds, I do not contradict them; I do not say, "Oh! that is impossible." I take the statement as it is given, and mentally make my own deductions.

Here is a woman whose womb measures three and a half inches, who has fibroid nodules in the posterior wall of the uterus, and also a laceration of the perineum. This latter, however, is not sufficient to demand the operation. She is not suffering enough to demand the operation. The change of life is coming on, and the nodules are not large enough to warrant the idea that she is going to lose much blood. There has boen an interval of a month since the last period, and perhaps the next may be longer than a month.

We shall order for her ten grains of chloride of ammonium ~~three times a day~~, and twenty drops of fluid extract of ergot three times a day. She will return in the course of a month, and report results.

The immunity of the colored race from cancer of the uterus is rather remarkable. Some of the southern physicians say that they have seen cancer in the colored race, but not so commonly as among the white race. They have another form of disease which the whites rarely have, that is keloid disease of the skin. I have seen this a number of times in colored people, but only once in the white race. Colored women are, however, very subject to fibroid tumors of the uterus. It is rare to find a fibroid tumor in a white woman before the age of thirty-five years, but in sterile colored women from the age of twenty to thirty-five, they will be found quite frequently, These tumors as a rule do not cause death, although a physician who sees a great many of these cases has to operate occasionally. In a case which I saw the other day, I found a fibroid tumor as large as a man's head in an unmarried woman of thirty-nine. She is losing a great deal of blood, and it is an anxious question to decide what is best to be done. Her physician states that during the past few months it has been growing rapidly. Now a fibroid tumor which increases rapidly in size may become so large as to interfere with any operation.

In operating for fibroid tumor of the uterus an exploratory incision is made, and if the tumor is found to have a pedicle, this is tied and the tumor removed and the wound closed, just as in the removal of an ovarian tumor; and this ought to be as successful an operation as removal of ovarian tumors. It is, however, rare to find a fibroid tumor with a pedicle. They usually spring directly from the womb. When this is the case, the proper plan is to remove the ovaries, which is a simple operation. By so doing, not only is menstruation stopped, but large blood vessels passing to the uterus are ligated, and in this way the blood supply is to a great extent shut off from the tumor, and in the great majority of cases it will diminish greatly in size. I have performed the operation a number of times, and have failed to check the hemorrhage in only one instance, and in this case the tumor proved to be malignant. If the tumor is allowed to become too large, it may render the operation impossible. Two years ago I operated on an enormous fibroid tumor in a white woman of thirty. I had seen her a year previously and had urged the operation, but she preferred to wait. At the time of operation the tumor filled the abdominal cavity, and must have weighed forty pounds. I had to make the incision from the ensiform cartilage to the symphysis in order to get the tumor out of the abdomen. The ovaries were attached to the tumor, and one of them was stretched to a length of six inches. It was a very serious operation, and the girl died in forty-eight hours. I have always regretted that I did not remove the womb in that case, although the result might have been the same. When the tumor is not large, it is possible to get at the ovaries without much difficulty. In these cases the ovaries and Fallopian tubes will, as a rule, be found to be diseased. Very often the tubes are cystic. When the ovary is affected it is often a follicular degeneration in which the capsule is thickened and the follicles are enlarged and project from the surface, or else an interstitial degeneration in which the organ is enlarged, roughened, and hardened, cirrhotic in character.

Dysmenorrhœa: Rapid Dilatation.

Here is a patient thirty-one years of age, married and sterile, who has had a great deal of pain since the time of puberty. This has been so bad as to incapacitate her for work, and it has been growing worse and worse. Why should she have pain, and why should it grow worse? If an unmarried woman, or a woman who is married and sterile, comes to you with a history of dysmenorrhœa, what should pass through your mind? That it is a dysmenorrhœa from anteflexion; that it is due to a stenosis caused by the womb bending too sharply towards the front—towards the front because she has never borne children, and the natural position of the womb is slight anteflexion. This is an exaggerated condition. There are very few exceptions to this rule. Sometimes there is retroflexion. As a rule, you will find anteflexion. The dysmenorrhœa is mechanical, and it usually gets worse after marriage. The woman may have been able to get along pretty comfortably before marriage, but afterwards the pain becomes worse and worse. Nature intended that when a woman got married she should become pregnant, and if a married woman does not have children, she nearly always suffers.

The pain of dysmenorrhœa, due to stenosis, is

usually of that character. It gradually becomes worse until it culminates, and when it reaches the highest point, there is a sudden gush and the pain subsides. Then it begins again and reaches another culmination, which is followed by a gush and relief. The womb is bent. The menstrual blood tries to overcome the bend, but it cannot do so until it has straightened the womb. After the womb is sufficiently distended to remove the bent condition of its neck, there is a sudden gush of fluid followed by relief. The same thing is seen when a rubber tube is bent; the water flows through the tube until it reaches the bent portion, when it is arrested until the force behind becomes sufficient to straighten the bend, and thus overcome the obstruction. The pain is due, not only to the distention of the womb, but also to the efforts of the organ to force the blood out of its cavity. This causes thickening of the endometrium, which in turn tends to increase the difficulty. When a woman suffering with this form of dysmenorrhœa gets married and does not bear children, the congestions arising from sexual intercourse will cause greater thickening and hypertrophy of the lining membrane of the womb, and consequently the cervical canal becomes still more contracted. There is not only thickening of the endometrium, but also hypertrophy of the parenchymatous structure of the womb. Then there is congestion of the ovaries, and structural changes following on this congestion. These changes may either result in follicular or interstitial degeneration.

I shall now make a physical examination. The first thing I detect is a virginal cervix. It is not thicker than my little finger. The os is very small. With a little manipulation, I get the sound past the bend and obtain the measurement of three and a quarter inches. This increased length of the womb has been produced by the dysmenorrhœa.

I propose to operate for this trouble to-day by forcibly dilating the neck of the womb. The cutting operation is the one usually recommended in the books, but that is a dangerous operation, and is by no means as successful as forcible dilatation. I have notes of one hundred and fifty cases in which I have performed this operation, and there has not been one fatal result, and in but one or two has there been any pelvic inflammation. To show you the result of the operation, let me refer to a case on which I operated a number of years ago. A clergyman's wife came to me suffering greatly with dysmenorrhœa. She had been married several years, and was sterile. I dilated the canal and heard no more of the case until a few days ago, when I saw her physician, who told me that after the operation she had gone home, and the first year had twins, and has been having children ever since. I have had a number of such cases in which pregnancy followed the operation. In the majority of cases, it is not necessary to perform the operation more than once, provided it is done thoroughly under ether. Women often object to taking ether, and want me to do it in my office without ether. I tell such patients that the operation gives a great deal of pain, has to be repeated frequently, and is very imperfectly performed under such circumstances. I tell them of the man who had a dog of which he was very fond. The dog had a long tail, greatly disfiguring him. The tail had to be cut off, but the owner of the dog disliked to give the dog so much pain—he therefore concluded to take off an inch a day until a sufficient length had been removed.

I shall first take this Ellinger's dilator and tunnel my way into the womb. First, introducing the dilator as far as it will go and dilating to that point, then pushing it a little further, I again dilate, and in a few minutes the instrument passes the internal os. Sometimes when the os is too small to admit the entrance of the dilator, I enlarge it with the scissors, keeping the blades closed, and using them with a boring motion. As I remove the dilator, you observe that a quantity of thick mucus follows its withdrawal. Whenever this is seen it is an evidence of obstruction. I shall now introduce the larger Wilson's dilator. In buying a dilator of this kind, you should be sure to see that it has these little shoulders on the blades to prevent it slipping too far into the uterus; for if the blades should come in contact with the fundus of the womb and be separated in that position, there would be risk of producing serious injury. After dilating up to a certain point, I wait a while. In all the cervices that I have dilated, I have torn only two. One was in a virgin and produced a slight laceration. The other was in a case which had been treated by the application of nitrate of silver until the tissues had been made brittle by the formation of cicatricial tissue. In that case a slight laceration was produced, and the bleeding was free enough to require the application of Monsel's solution. That is the only case in which I found it necessary to apply any styptic.

Sometimes I get hold of a very small cervix, one which is really infantile. Under such circumstances I do not expand the instrument to its fullest capacity, for fear that I may tear the cervix. In the majority of cases, however, I dilate to the fullest extent of the instrument. This gives an os through which the finger may be passed to examine the interior of the womb, and in many cases this is better than dilating with sponge tents. There is not the same danger as exists with sponge tents. On the other hand, tents will dilate to a greater extent. After a dilatation of this kind, I can often introduce my finger into the womb, although I am not usually able to do so in sterile cases.

I have now separated the blades of the dilator to their fullest extent. I shall remove the ether and allow the instrument to remain until the woman begins to flinch. Just before beginning the dilatation, I introduce a suppository of one grain of the aqueous extract of opium into the rectum, so that by the time the operation is completed the suppository will have dissolved and the opium be absorbed. At first the pain is great, but it soon subsides. Usually two suppositories are all that is required, one being given at the time of operating, the other two hours afterwards. If the pain continues, the opiate must be repeated. If there is much soreness, I have a poultice placed over the abdomen. I always like to keep these patients in bed for forty-eight hours. For the first twenty-four hours I order a light diet, and after that the patient returns to her ordinary food. If the soreness continues, I keep them in bed until it disappears.

The woman is now beginning to show evidence of feeling the pain, and I shall remove the dilator. It is very probable that some of the muscular fibres have been ruptured. I know that some of them have been over-stretched and will never contract as before. There is, as you see, a little oozing of blood, but I shall not attempt to check this, for I consider a little bleeding an advantage, as it tends to prevent the occurrence of inflammation. I have never had severe metritis or peritonitis after this operation. I have, however, seen slight localized inflammation follow it.

You will often be consulted by sterile women who want to have children. It is a mania with them. If a woman wants to have children, she will go through fire and water to become pregnant; and, on the other hand, if she does not want to have children, which I am sorry to say is the crying evil of the day, she will go through fire and water to prevent conception. If a woman wants children, all her friends know of it. Sometimes this operation will enable such a woman to become pregnant. At times, however, the condition has lasted so long that changes in the uterus have been induced which effectually prevent conception. If you are fortunate enough to enable her to have children, she will blazon your name and skill all over the neighborhood.

If this operation is done carefully, I can recommend it most confidently. It is much safer and far more successful than the cutting operation, which I am happy to say is now rarely performed.

Fibroid Tumor.

This patient was before the class two weeks ago suffering with a fibroid tumor of the womb, with a great deal of hemorrhage. You can see the effect of loss of blood in her countenance. Her complexion is very like that of carcinoma. It has a leaden hue. If she lived in a malarial district and was impregnated with the malarial poisoning, she might have the same sort of a complexion although, perhaps, a little darker. She is forty-four years old and unmarried. The menses return every two weeks, and she loses a great deal of blood. For the past four or five years, the bleeding has been much worse than before. If she were a married woman and had borne children, we should have at once suspected carcinoma; but being forty-five years of age, unmarried and with this bleeding, the probabilities were in favor of a growth of some kind. On making the examination, a fibroid tumor on the right side of the womb was found. We concluded that the tumor was partly mural and partly submucous.

She was given ammonium chloride and fluid extract of ergot. She states that she is improving. The best thing to do in this case would, I think, be to remove the ovaries, for then the patient is cured almost at once, and is able to attend to her duties. The woman is, however, not willing to have the operation performed, and we must therefore endeavor to check the growth of the tumor and keep the woman alive until the change of life occurs, which will probably take place at about fifty.

The womb measures five inches, and the tumor is not a large one; this shows that it is submucous and more or less mural. It occupies the posterior portion of the womb. The os is dilated so that I can introduce the tip of my finger.

If the use of ammonium chloride and ergot fail to check the growth and control the bleeding, one of two things could be done. The os might be dilated so that the tumor could be reached and enucleated. There is, however, an objection to this, in the fact that rarely is there only one large tumor, but there are many smaller ones; so that when the large one is removed, the others spring into growth and the trouble is reproduced. The other operation is removal of the ovaries. By removing the ovaries, the change of life is brought about.

We shall place this patient on the hypodermic use of Bonjean's ergotin. The injections will not be made in the median line, which is the best place, but to one side. The object of this is that in case we find it necessary to perform oöphorectomy, there will be no hardened and thickened tissues in the line of the incision.

The operation of enucleation of a fibroid is more dangerous than the removal of the ovaries. The patient is forty-four years old, and even if she should marry, she could have no children. Even after enucleation of a fibroid, I have never known pregnancy to take place.

As I have said, we shall try the use of ergot. This sometimes increases the flow of blood at the monthly periods. If it acts in this way, it will have to be discontinued, and reliance placed upon other remedies. There are three to fall back on when ergot fails. The first that I shall mention is oil of erigeron. This may be given in doses of five drops on sugar, or better in capsules, repeated every hour until bleeding is diminished. The next is digitalis. This is an excellent remedy, if its effects can be watched. It should be given in ten-drop doses every two hours until it produces the desired effect, or the patient has some trouble with vision or some of the symptoms of the systemic action of the drug are produced. In my experience, the first symptom produced in cases of this kind is blurring of the sight. The third remedy is gallic acid in very large doses—from ten to twenty grains—repeated every two, three, or four hours, according to circumstances. An objection to this remedy is the obstinate constipation produced.

There is another remedy which I might mention, and that is quinine with sulphuric acid. I give them separately, giving the sulphuric acid in the form of the aromatic sulphuric acid in doses of twenty drops every two hours. The quiuine I give in doses of two grains every two hours. This is not as efficient as the liquid preparations of quinine, but I always make it a rule in giving quinine or other bitter or nauseous drugs to administer them in pill form. This is a general rule which you will do well to adopt; never give unpleasant medicines when it can be avoided, and when you have to do it, give them in as pleasant a form as possible. For instance, never give castor oil unless there is some positive indication for it.

If you have a hemorrhage which is not checked by ergot, give oil of erigeron; if this fails, try digitalis, gallic acid, or quinine and sulphuric acid.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, April 3, 1884. The President, R. A. Cleemann, M. D., in the chair.

Dr. Cleemann made some remarks on the subject of

Digital Dilatation of the Os Uteri During Labor.

He had been taught not to dilate or stretch the os uteri with the finger, and for years this early teaching deterred him from making any attempt to supplement the contractile powers of the uterus by assisting in the process of dilating the os. Some time since he was called to attend a primipara, the waters had been discharged the previous day, the pains had continued, but the os uteri was very small, and the cervical rim hard and unyielding. He felt called upon to interfere actively, and tried to dilate the os with his finger; it softened rapidly, and in half an hour was sufficiently dilated to allow the head to pass, and delivery rapidly followed. Since that occasion he has tried the same procedure on several cases, and always with gratifying results, the labors being brought to rapid terminations, where previously hours had been wasted in weary and painful waiting. The irritable condition of the os which had been lectured upon as the consequence of such interference, has not been experienced; no injury has resulted in any case. The soft finger can do no more harm, if clean, than a Barnes' or other form of dilator; and there is no danger, as in the case of the latter, of pushing the head aside and converting a vertex into a shoulder or other faulty presentation.

Dr. W. T. Taylor, since he had dared to deviate from the teaching of Professor Hodge, had used his finger to assist the dilatation of the os; he did not do so if the cervix was irritable, or its edge wiry.

Dr. Githens had practiced digital dilatation of the os uteri throughout his obstetrical practice, a period of eighteen years. He does not confine it to any class of cases, nor does he wait until after the membranes are ruptured. In any or all cases he finds that a "pain" is accompanied by a contraction of the circular muscular fibres of the cervix, as well as by a contraction of the longitudinal fibres of the body of the uterus. The contraction of the circular fibres retards the progress of the labor. The intention of the digital distension is to paralyze these circular fibres, and thus favor the dilatation of the os. In practice this effect is rapidly produced. One or two fingers are swept around the inside of the cervix, the pulp of the finger being next the cervix, and the alter is pulled away from the head. This operation is kept up during the interval between pains; when the pain occurs the finger is withdrawn; the operation is repeated in the next interval. The membranes are not ruptured by this process. Irritable condition of the os, if such exists, is subdued. If the rim of the cervix is wiry and thin, or hard and thick, it softens and yields; the cervix and vagina, if hot and unyielding at first, become cool and pliant; cervical tears are almost entirely avoided, and the time, pain, and exhaustion of the labor are reduced to a minimum. The process is useful in every case of labor throughout the first stage.

Dr. Philip M. Schiedt practices digital dilatation largely. His patients say they recognize the assistance it gives them, and in subsequent labors ask the doctor to help them. By the great shortening of the first stage of labor resulting from this method, the use of the forceps is frequently avoided.

Dr. Parvin would be sorry to see digital dilatation adopted as a rule for all cases. "The fingers used as recommended do not act only, possibly not chiefly, as dilators, but by evoking uterine contractions." Voluntary efforts at bearing down are not needed during the first stage; they are dangerous rather than helpful. The method may be useful in some cases after the rupture of the membranes, which is the natural dilating agent. There is also danger of septicæmia from germs on the fingers. He does not think "the fingers so good a dilator as Barnes's dilator," because unequal partial pressure upon the os does not evoke the decided uterine contractions that general uniform pressure does. He thought the danger of a change of presentation by the use of Barnes's dilator very slight. He would prefer a mechanical dilator to the finger whenever dilatation was necessary, but thought something ought to be left to nature. Any sort of interference carries a possibility of danger.

Dr. Elliott Richardson thought there was a possible danger of rupturing the membranes. Our authorities caution us about the introduction of the finger into the uterus and the too early rupture of the membranes.

Dr. Harris remarked that one point had been overlooked. Why does the os not dilate easily when the head is the dilating agent? It is because it is a round surface, over which the cervix does not slide easily. On the contrary, the finger is applied at successive points. One benefit of the method is that any change or danger is at once detected. The method should not be used indiscriminately, and we should not interfere unnecessarily.

Dr. Cleemann would not recommend the method in every case of labor. He has resorted to it in cases where there has been early rupture of the membranes and the assistance of the bag of waters has been lost. In a recent case he saved a patient hours of suffering, and the os was not bruised or injured in any way. The sight of any instrument causes the patient much anxiety, and the exhibition of the Barnes' dilator, and the water, syringe, etc., cause nervous excitement. The bags sometimes burst and thus give the patient a terrible shock, with the added discomfort of the escaping water or air. He has always carried them, but does not like to use them.

Exanthematous Disorders in the Puerperal State.

Dr. Parvin had recently an experience of the invasion of measles and scarlet fever in the Obstetric Wards of the Philadelphia Hospital. In the first case in which measles occurred, he did not think that the full term of pregnancy had been reached. Authorities state that premature labor is usually caused, as a result of the high temperature of the exanthematous fever. One patient had septicæmia in addition, but recovered.

The infants were not affected. In one case, soon after labor the temperature rose to 103°, and the patient was sent to the Fever Ward. At the second visit, a slight rash was observed, which subsequently proved to be scarlatina. Desquamation was very abundant. Albuminuria was very marked on the tenth day; rheumatic pains were also felt. The patient recovered. The child remained well. Children have been born with measles, but he did not know of such an experience with scarlet fever.

Dr. W. T. Taylor, some fifteen or twenty years ago, had reported in *Amer. Jour. Med. Science*, 1853, a case of congenital small-pox. The mother had some febrile symptoms and pain in the back, and the child had the disease, being marked with pits. He had a case of scarlet fever in a mother two days after labor. It proved fatal in two days. The child lived.

Dr. Harris remarked that in the reports of the Rotunda Maternity Hospital, in Dublin, are a number of interesting reports on complications of the puerperal period by exanthematous fevers. Their mortality has been very materially influenced by these epidemics. Erysipelas is the most interesting and most fatal of these complications; in some cases it resembles septic poisoning.

W. H. H. Githens, *Secretary.*

Thursday, May 1, 1884, the President, R. A. Cleemann, M. D., in the chair.

Dr. Henry Bates, Jr., read a report of a case of

Cystic Leiomyoma Uteri,

the fluid of which contained Drysdale corpuscle and other characteristics of typhoid ovarian cystoma.

The early history of this case, owing to the inability of the patient to state with precision a few minor details, is somewhat incomplete, yet sufficient accuracy is available to supply a clear, unequivocal clinical record, and distinctly demonstrate that the Drysdale corpuscle, when found in considerable number in fluid derived from the abdominal cavity, is not pathognomonic of cystoma ovarii.

Mrs. L——, aet. 51; housewife; a mother; noticed, four years prior to admission to the Philadelphia Lying-in Charity Hospital, a lump in the lower abdominal region. The menopause had not yet occurred. The tumor was round, painless, and occasioned no inconvenience. Its development was comparatively slow, and not until it had attained large dimensions did it occasion constitutional derangement. When admitted, the patient was markedly asthenic, and suffered from mechanical dyspnœa, gastric irritability, subacute proctitis, and pyrexia; the temperature ranging from 99° to 100.5°.

The facies ovariana and the peculiar atrophy of the soft tissues of the supra-thoracic region, so constant an attendant upon ovarian cystoma, were present in conspicuous degree. The notes of measurement are unfortunately lost; but an estimate of the size can be formed when it is remarked that the tumor completely occupied the abdominal cavity, everting the xiphoid cartilage and inferior ribs, bulging far over the lumbar regions, and extending over the pubes down and between the thighs. The circumference, at its largest portion, was about fifty-one inches. The superficial abdominal veins were conspicuous, and the cellular tissue from the mammary zone to the feet very œdematous. Palpation and percussion detected and revealed signs of ovarian cyst. The fluctuation was more perceptible in the longitudinal than transverse diameter. In the subhepatic region, a decided resistance to pressure was noticeable, dependent upon a thickening of the cyst wall. This mass was attached to the liver at the outer two-thirds of the inferior border. At the inner third there intervened a space which emitted a percussion tympany, the note being that of colic resonance. The urine afforded negative evidence. As the asthenia was so profound, it was deemed advisable to tap the cyst in order to obtain an opportunity of improving the general strength and rendering ovariotomy bearable. Dr. Albert H. Smith, who had charge of the case, tapped, employing the ordinary curved trocar and cannula used in tapping per rectum the urinary bladder, and withdrew twenty-seven pints of a dark, muddy-brown grumous fluid, possessing a neutral reaction; sp. gr. 1018, and containing blood and paralbumen. Microscopically I found red blood corpuscles, leucocytes, endothelium in various degrees of retrograde metamorphosis, *i. e.*, the corpuscles of Bennett, Nunn, and Gluge, the ovarian cell of Drysdale, cholesterine and amorphous detritus. It did not coagulate spontaneously. These micro-chemical properties coupled with the physical signs determined a diagnosis of ovarian cyst. The grumous character of the fluid and the existence of the sub-hepatic mass inclined to the belief that we were dealing with a cyst in which carcinosis had become established, and that either metastasis to the liver occurred, or that there co-existed carcinoma hepatis. The idea of ovariotomy was abandoned and analepsis instituted, with the effect of improving the general condition sufficiently to enable her being removed to her home, where she remained under the care of Dr. L. Brewer Hall. In about five months the tumor had refilled, and during my absence Prof. James B. Walker, at Dr. Hall's request, tapped a second time. The fluid was clear, and presented the appearance of ovarian fluid. In the winter of 1882 I tapped a third time, employing an aspirator. The gentleman assisting me inadvertently applied the exit nozzle of the air-pump to the vacuum jar, and when the trocar was introduced there occurred an inflation of the cyst. The air apparently inflated a series of variously sized cysts that were arranged circumferentially and emitted percussion notes of different pitch. From this circumstance, which occasioned no evil consequences, we concluded that there existed a number of small cysts communicating with the principal. As the evacuation of the fluid progressed, the umbilical region sunk in, disclosing a circumferential mass presenting the appearance of a wreath, as it were, underlying the abdominal parietes. This ridge could be firmly grasped, and moved to a limited extent. This peculiarity determined me to carefully examine the fluid. I also had Dr. Formad examine it, and he pronounced it ovarian. The class at the University of Pennsylvania was supplied, and the ovarian cell of Drysdale demonstrated. The cyst refilled more rapidly, and I tapped a fourth time, removing a large bucketful of clear fluid, containing the

same corpuscle in greater number than the previous specimen. Large flakes of coagulated lymph were also evacuated. The circumferential mass had undergone great development, as had also the sub-hepatic induration. The re-accumulation of fluid was more rapid, and the deterioration of health steadily progressing. Death terminated suffering about six years after the first manifestations. During the last days of the patient's life, Prof. Walker, in the absence of Dr. Hall, was in attendance. His letter details the mode of death and results of the autopsy:

"Mrs. L. died on the Sunday night after your departure. Her bowel trouble rapidly disappeared, but the symptoms of cerebral anæmia deepened with hallucinations and convulsions until death.

"At the autopsy, the tumor was found to have membranous walls over an area of nine square inches above the navel in the middle line; elsewhere the cyst wall was thick as per sample. In some localities, notably in the hypochondriæ, the wall was quite thick. Firm attachments existed over the anterior wall of the sac with the parietal peritoneum, and the intestines were carried far up under the liver and stomach, and were attached to the tumor. The liver was also attached. The entire abdominal cavity was occupied with the tumor, and it dipped into and occupied the pelvis. No attachments existed at the sides nor behind. The uterus was forced downward. One ovary, the right, was normal and attached loosely to the pelvic brim. The other is presumably occupied by the tumor. The cavity of the tumor was occupied by a brownish gelatinous fluid resembling soft soap; it was transparent, but had a sediment consisting of detritus from the inner wall of the sac. There was but one cyst, and the entire interior was similar in its lining, being apparently undergoing erosion. The contents of the cyst measured over a Yankee bucketful. As the tumor was too immense to even contemplate removal, and as the variably thick wall was everywhere similar, save in the pelvic portion, which was darkened from hypostatic congestion, I removed the uterus and the portion of the tumor immediately surrounding it, extending the section through the cyst wall." (This specimen was presented to the Society.) Sections for microscopic study were prepared from different portions of the cyst wall, and were all demonstrative of leiomyoma. Those from the sub-hepatic portion resembled spindle-celled sarcoma, but were clearly differentiated by the elongated nuclei and want of sorcomatous relationship of cells to capillaries. The identity of the clinical phenomena of this neoplasm with those of ovarian cyst is a matter of special attention. In the early stage a marked peculiarity consisted of the sub-hepatic enlargement and induration; a morbid resistance to pressure noticed in the inferior lumbar regions after the first tapping and attributed to the œdema, is now seen to have depended upon a thickening wall, which at that time was insufficiently developed, save in the hepatic region, to attract special attention. That all doubt regarding the nature of this neoplasm may be removed, attention is directed to the left ovary, which has undergone marked atrophy, and is to be seen in the specimen. I submitted some sections to Dr. Formad, who pronounced them ovarian. The origin of the cyst from the fundus uteri is evident upon examination. With the facts before us, I think it is conclusively proven that the ovarian corpuscle of Drysdale, while a valuable aid to diagnosis, does certainly not possess pathognomonic value.

Periscope.

A Plea for More Heroic Surgical Interference in Affections of the Brain.

Dr. R. W. Amidon thus recapitulates an article on this subject in the *Medical News*, June 21, 1884:

We have trephining, an operation proving fatal in only three per cent. of published cases:

Opening the dura mater, fatal in only 7.6 per cent. of published cases:

We have the brain, an organ tolerant of injury and ready to take on a reparative process:

We are possessed of a knowledge which enables us to tell when certain parts of the brain are diseased; and we also have anatomical data which tell us just where to pierce the envelopes of the brain to reach a certain definite part of its convexity.

We have all the elements of safety and anatomical accuracy: why should cerebral surgery not advance with pulmonary, renal, intestinal, and ovarian surgery?

My allotted time and space are exhausted, and I close with a few practical remarks suggested by the subject in hand.

The substitution of the dental engine and a burr or drill cutting on the side for the ordinary trephine strikes me as advantageous. It has been used and advocated by Dorr* and Roberts.† Its advantage over the trephine is principally that with it you can cut away as much or little bone as you please, and make an opening of any shape you please. It is especially useful in trimming down the edge of over-riding bone, to allow the elevation of depressed fragments.

Let the operation always be done with antiseptic precautions. Try and secure only approximate coäptation of the flaps. Provide the freest possible drainage. Use cold antiseptic dressings, without much compression. Enjoin the strictest quiet in a posture facilitating drainage. Simple diet, and a slightly loose condition of the bowels.

*Buff. Medical and Surgical Journal. 1879–80, vol. xix., p. 475.

†Philadelphia Medical Times, 1881–82, vol. xii., p. 206.

On the slightest rise of arterial tension or temperature, give jaborandi or aconite to the production of physiological effects. Quinine and alcohol should, I think, be given only in tonic doses. An anodyne is often indicated, and it is my advice never to use opium, or any of its preparations or derivatives. To ease pain, quiet delirium, or induce sleep, use the hydrate of chloral in small repeated doses (.60–1, every ten or fifteen minutes). Quinine and alcohol in large, and opium in *any* dose, aggravate intracranial inflammation when present, and, I think, may excite it.

These suggestions apply equally well, or with still greater force, to cases in which the dura mater or brain is accidentally or intentionally invaded.

A few words as to what I consider good indications for opening the skull.

An injury of the vault, however slight the marks of external violence, provided there be coma, aphasia, hemiplegia, or hemispasm of the lower part of the face, of the arm, or leg, or all three, constituting hemiepilepsy; whether accompanied or not by chills, fever, headache, and vomiting. General epileptic convulsions do not constitute so good indications for operation. Every case of compound fracture of the skull, whether there be cerebral symptoms or not. Cases in which, after the lapse of months, or years even, unmistakable cerebral symptoms follow an injury to the head. Atrocious and incurable headaches, particularly if localized, aphasia, monoplegias and monospasms, hemiplegic or hemiepileptic seizures or general epileptic attacks, if they have an aura pointing to a localized lesion. In addition to the bone, the dura mater should be opened, in all cases in which exploration with a hypodermic needle discloses the products of purulent inflammation or a great deal of fluid blood under it. In all cases in which a serious lesion of the brain is suspected, but cannot be otherwise proven.

In addition to the bone and dura mater the brain should be explored, delicately with a probe, in all penetrating wounds of its substance, punc tured, lacerated, or gunshot. Its mass should be invaded, even when superficially intact, by a fine, blunt exploring needle, when the presence of foreign bodies or hidden collections of pus are suspected, and, for the extraction or evacuation of such, larger openings should be made with a dull instrument.

Finally, accessible neoplasms of the brain, which have resisted medicinal treatment, and which continue to grow and threaten life, should be removed for the reason that they are generally single, seldom have secondary deposits, are surrounded by an inflammatory zone of demarcation, and *always* kill by pressure.

A Simple and Successful Method of Treating Fracture of the Clavicle.

Dr. S. J. Allen, of White River Junction, Vermont, says in the Transactions of the Vermont Medical Society:

Few doctors boast, when fracture of the clavicle is discussed. Both professional and lay refer to it with qualms of the solar plexus. A glance at the lists of deformities, tells how much we lack in its successful treatment.

All methods heretofore practiced or published involve one general principle—namely, raise the shoulder up and back, and keep it there, if you can. Various dressings and appliances have been devised to accomplish this object, but every intelligent *surgeon* will admit that all methods for the treatment of this fracture have not, with few exceptions, been successful. To keep the shoulder up and back, by whatever dressing applied, is an impossible thing to do, as a rule. The fragments can readily be restored and placed in the closest relations; but the least movement of the head, neck or arm, is often sufficient to separate them.

The seat of the fracture is usually near the middle of the bone, as it is thinnest and weakest at this point. Eight of twelve occur at the middle; three towards the acromial, and one towards the sternum. In fracture at or near either extremity, the loss of apposition is usually very slight, owing to the manner in which the bone is attached to the scapula and sternum; consequently the difficulty generally is in the successful treatment of this fracture at the middle part of the bone. In fracture of the clavicle at the middle, the outer fragment is drawn downwards and *inwards* by the weight of the arm and by the action of the deltoid, the small pectoral, and the subclavian muscles. The inner fragment is raised by the muscular contraction of the sterno-cleido-mastoid.

The following described method has been successful in the hands of many others in this region besides myself, in the treatment of this fracture, without resultant deformity. The principle involved in the method described is directly opposite the principle set forth in every method heretofore published and practiced. The object, of course, is to *keep* the fragments in close apposition until union is complete and firm.

Cut a strip of surgeon's adhesive plaster, Seabury & Johnson's, Martin's, or other, eighteen inches long, and two and a half inches wide. Fold the strip of plaster *sticky* side out, so as to make a compress-pad of equal dimensions. Then cut two other strips three inches wide, each, and two feet long—longer or shorter, according to the size of the patient. Raise the shoulder up and back, so as to bring the fragments into apposition. Have an assistant hold the shoulder immovable in this position, whilst the surgeon applies the dressing. Place the compress on the site of the fracture. The heat of the skin will make the compress-pad adhere, whilst the surgeon applies the rest of the dressing. First apply one of the strips of plaster, commencing on the front of the thorax, so that the part that goes over the shoulder shall be equidistant from each end, and continuing it down the back part of the chest, drawing it taut enough to hold the fragments firmly in apposition. Then apply the other strips in the same manner, but in such relation to the first strip that it shall cross it obliquely directly over the compress.

The adhesive plaster compress or pad, folded sticky side out, and applied to the seat of fracture, and held firmly in place by the strips, as above directed, becomes, so to speak, an element in the anatomy of the parts. The compress adheres firmly to the part to which it is applied, and is absolutely immovable; the dressing holding the fractured fragments accurately in apposition long enough to secure union without deformity.

This method is equally successful in the treatment of dislocation of the clavicle and fracture of the acromion process.

The Treatment of Coryza.

Dr. G. E. Dobson writes as follows in the *Lancet*, May 31, 1884:

"This very troublesome complaint has scarcely received the attention it deserves, if we take into consideration the great number of sufferers and the serious laryngeal and pulmonary diseases to which it is too often a prelude. Amongst a host of remedies proposed for its abortive treatment, most of which are either of doubtful value, or else difficult to procure or apply, or even dangerous to use, not one can be named of which it may be said that it is at every one's command, easy of application, unattended with danger, and really effective. No excuse is, therefore, needed in introducing to the notice of the profession the following simple yet thoroughly effective mode of treatment, which in my hands has never disappointed expectation. About a drachm of camphor, coarsely powdered, or shredded with a knife, is placed in an ordinary shaving jug, which is then half filled with boiling water. The patient, having made a paper cone (out of a sheet of brown paper or an old newspaper) large enough to surround his face by its wide extremity and the mouth of the jug by its narrow end, proceeds to respire freely, at each inhalation drawing the steam into his nostrils, and at each exhalation forcing it up against the outer surface of his nose and adjoining parts of the face. A twofold action is produced: the camphorated steam acts internally in a specific manner upon the whole extent of the mucous surfaces, and, externally, produces profuse diaphoresis of the skin covering the nose and sides of the face, there acting as a derivative from the inflamed Schneiderian membrane. The jug should be surrounded by a woolen cloth in order to prevent the water, cooling, or, better, if a tin shaving-can be used, a small spirit lamp or heated iron may be placed beneath it, so as to maintain the heat of the water and the vaporization of the camphor. The patient should continue his respirations (keeping the margins of the base of the paper cone closely applied round his face) from ten to twenty minutes, and this should be repeated three or four times in as many hours, till entire freedom from pain is experienced. Great relief is always felt even after the first application, and three or four usually effect a cure. Camphor, or some of its preparations, have, as is well known, been long in use in the treatment of colds, but the above-described method of employing it in conjunction with the vapor of water both as an internal and external application at the same time, has not, so far as I know, been previously brought to the notice of the profession, or, if brought, has not been recognized in any general or special medical work. The mode of application is, however, all important; but as this is neither troublesome nor otherwise unpleasant to the patient, nor are the materials difficult to procure, camphor being everywhere a household drug, I believe that those who may give this treatment a trial will find it not only a simple, but also a most effective, remedy against coryza."

Large Doses of Carbolic Acid in Puerperal Septicæmia and Enteric Fever.

Dr. Alexandra V. Samoilovitch, of Tiflis, furnishes a detailed account (*Proceedings of the Caucasian Medical Society*, 1883, No. 11) of two interesting cases in which she made rectal injections of large doses of carbolic acid. One of her patients, a strongly-built and well-nourished lady, twenty-two years of age, suffered from a severe form of puerperal septicæmia, with endo-, para-, and perimetritic foco; in addition to which, on the fourteenth day of the disease, there appeared erysipelas of the buttocks and external genitals, and, on the sixteenth, pleuro-pneumonia on the left side. By the twenty-first day, all medical attendants of the patient unanimously declared her state beyond any hope. In spite of the administration of quinine and subcutaneous injections of 2½ per cent. solution of carbolic acid (as recommended in puerperal fever by Dr. William Polk, in the *Centralbl. für Gynæcologie*, 1883, No. 5), the temperature stood as high as 41.3° C. (106.16° F.), the pulse (160 a minute) was small, irregular and intermittent; respiration shallow, 40. The patient was cyanotic, and went from one fainting fit to another. It was under these extreme circumstances that the author tried, as her last means, an energetic administration of carbolic enemata. The latter were made of six grains of carbolic acid, a drachm of spirit, five drops of tincture of opium, and one and a half ounces of water. Three successive enemata (that is, eighteen grains of phenol) were administered in two hours' intervals. Five hours after the first injection the temperature fell from 41.20° C. to 38.7° C. (101.6° F.). From this day an interrupted, though slow, recovery set in. The other case was that of a strong male patient, aged 31, affected with typhoid fever. The injections were made during the second week of the disease, and contained from 6 to 12 grains of carbolic acid. Twelve-grain enemata invariably produced profuse perspiration and reduced the temperature about 1½° C.; headache disappeared, and quiet sleep followed. In neither of the cases were any toxic symptoms present.

Alvelos: A New Cure for Cancer.

The *Therapeutic Gazette* for May, 1884, says:

The statement that any remedy has been discovered which will obviate the necessity of a resort to the knife in the treatment of cancer, will be met with incredulity, and in giving the following from the *Lancet* we give it without comment and simply for what it is worth: Dr. Velloso, of Pernambuco, introduced the remedy to notice in a communication to the *Journal de Receife*. He states that the plant, which is commonly known by the name of alvelos, belongs to the euphorbiaceæ, and is indigenous to Pernambuco. He writes that a magistrate, who was suffering from epithelioma of the face, and who had returned to his estate despairing of relief, was entirely cured of his disease by the topical application of the juice of the plant. On the strength of this report Dr. Vellosa tried the remedy in the case of cancroid of the nose, and in one of epithelioma of the lip, with the result that the first patient was completely cured in forty days, and the second in less than two months. These results, he thinks, justify a

trial of the remedy, especially in uterine cancer. The action of the juice of the plant is irritating, producing a spreading dermatitis without much pain, and the application of the cut stem or the juice of the fresh plant to the diseased part, is said to result in the destruction of the morbid tissue, which is replaced by healthy granulations, doing the work, in fact, of the chloride of zinc paste.

It is clear that if the remedy possesses only escharotic action, its value cannot be said to be very superior to that of other well-known caustics. The fact, moreover, that only the fresh juice of the plant produces the effects claimed, must, limit its use very largely to the region in which the plant grows.

A Himalayan Hypnotic.

In the *Popular Science News* for May, 1884, we read that in the course of a recent discussion in the London Medical Society on the cold-bath treatment of enteric fever, the president, Sir Joseph Fayrer, handed round, as bearing on the subject, two sketches which had been sent to him by Surgeon-General Townsend, C. B. They represent a plan of putting young children to sleep, followed in many parts of the Himalayas. "Near almost every village," said Sir Joseph Fayrer, in explaining the sketches, "there are one or more small channels by which the water from the neighboring spring is conducted to the cultivated plots of ground, for the purpose of irrigation; and these channels are, in parts, formed of troughs hollowed out of fir-trees. A piece of bark or matting is laid on the lower of two of these troughs, and on this the infant, swathed in a large mass of clothes, is so placed that the water from the upper trough falls on the vertex of the cranium, and, glancing off thence, runs away under the bark or matting without further wetting the child or its clothes. Or, if the stream is full and copious, the child is placed on the side of the channel, and a portion of the stream directed on its head by a large leaf or piece of bark; another leaf or piece of bark being arranged on the other side of the head so as to catch the water and carry it away. Children so placed will lie asleep for hours, and their mothers leave them while they go about their daily occupation. The child's head and face are much muffled up; little more than the vertex of the cranium, on which the water falls, being left uncovered."

Achillea Millefolium in Leucorrhœa.

Dr. Lvoff (*Vratch*, 1884, No. 2, p. 28) says that Achillea millefolium (of fam. *Compositæ*, trib. *Senecionideæ*), an old popular remedy, displays a decidedly beneficial action in cases of simple (non-gonorrhœal) whites in children and adult women. His statement is based on the administration of the plant to thirty-four patients, twenty of them being aged from 7 to 15, seven from 15 to 20, and seven from 20 to 30. An infusion of summits or flowers was used. In an editorial note, Prof. V. A. Manassëin states that according to Annenkoff the leaves and flowers of millefolium possess tonic and stimulating properties, and are used in atony of the digestive organs, in cases of hemorrhoidal and uterine hemorrhage, in dysmenorrhœa, mucous whites, chlorosis, etc. Ronzier-Joly praised the remedy as an emenagogue (10 grammes to 500 of boiling water). Chomel and Hufeland gave it as an antispasmodic and in amenorrhœa (20, 30, to 1000). Zanoni prepared from millefolium a bitter, alkaloid-like principle, achilleine, which was later studied by Planta, and was recommended as a remedy for intermittent fever by Puppi.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A Memoir on the Nature of Diphtheria, by Drs. H. C. Wood and H. F. Formad, makes an appendix to the recently-issued report of the National Board of Health for 1882. The results of a large number of experiments are tabulated, and it is evident that the authors pursued their investigations with great zeal. The fact remains, however, that the results obtained have not proved satisfactory, or at least not decisive on the questions examined. It is also unfortunate that the interval between the investigations and their publication has rendered a portion of this memoir already obsolete.

——The latest of the Health Primers published by D. Appleton & Co., New York, is entitled "Baths and Bathing." It treats of the physiological action of baths, their varieties, their uses, and the location of some of those in Europe. The little treatise has, like all others of this series, been carefully prepared by a competent hand, but with reference to English wants exclusively, and is not suited so well to the American public.

——Two remarkable cases in surgical practice are described in a reprint by Dr. J. T. Johnson, of Atlanta, Georgia. One of them is that of the ligature of the carotid artery; the other of a pendulous tumor in the sacral region, considerably resembling a caudate appendage, as is well shown in the wood-cut attached.

——The constantly recurring question of the responsibility of the insane for criminal actions is again discussed by Dr. O. Everts, of College Hill, Ohio, in a reprint from the *American Journal of Insanity*. We cannot say, however, that his essay throws any new light on this difficult problem.

——The official report of the relief furnished to the Ohio River flood sufferers in February and March last makes a pamphlet of 76 pages, as recorded by Dr. R. P. M. Ames. He gives a general

history of the flood and a description of the incidents occurring on the two trips of the government relief boat. His narrative is vivid and interesting.

——A strong argument to the effect that much of the febrile disposition characterized by temporary suspensions, is not really malarial, but in fact paroxysmal, is advanced by Dr. J. H. Musser, of Philadelphia, in a reprint before us. The subject is an important one, especially in its bearings on the much-mooted question of the prevalence of malaria.

——The Bureau of Education has recently issued some circulars on illiteracy in the United States, and on prison discipline, which merit the attention of all who are concerned in improving the condition of our nation.

BOOK NOTICES.

Transactions of the Medical Society of the State of Tennessee, 1884. Pp. 140. Nashville, 1884.

This volume is characterized by a number of original articles highly creditable to the members. Of these, we may mention one on the sequelæ of diphtheria, by Dr. W. M. Vertrees, containing the particulars of two cases of paralysis; one by Dr. H. Berlin on the development of modern therapeutics; a review of the hot-water treatment, by Dr. Mary T. Davis, who thinks very highly of this innocent remedy; one on puerperal fever, by Dr. A. J. Swaney; and a discussion of hospital gangrene, citing several cases, by Dr. J. R. Rathmell. The address of the President, Dr. A. B. Tadlock, is upon the progress of medical science, especially in Kentucky and Tennessee, and contains a number of interesting facts.

Report of Section on Surgery of Nebraska State Medical Society, 1884. Plattsmouth, Neb., 1884.

The Surgical Committee of the Nebraska Society have collected in this pamphlet a careful summary of the recent progress in surgical science, and have added to it various original articles by members of the Society. There are a number of illustrations, and the report will be found generally meritorious, although the printer has not done it justice.

The Laws of Health for Educational Institutions and General Readers. By Joseph C. Hutchison, M. D., LL. D. Pp. 223. New York: Clark & Maynard.

So far as paper, printing, and illustrations are concerned, we give this book unqualified praise. We regret to say, however, that the author's prejudices, especially on the subject of alcohol and tobacco, frequently lead him to conflict with the most reliable statistics of the effects of these agents. At times also other of his statements are strangely erroneous, as, for instance, p. 25, where he says, "Nature gives the same amount of muscles to every healthy person," going on to argue that difference in strength comes from use or disuse of the muscles. Again, p. 119, what sort of a definition of the cerebrum is it to call it "The seat of the mind?" Many such objectionable expressions, representing the mythical rather than the positive epoch of medical science, have caught our eye in glancing over the author's pages, and cause us to regret that he was not inspired by a more liberal and scientific spirit.

Practical Manual of Obstetrics. By Dr. E. Verrier. With Revision and Annotations by E. L. Partridge, M. D. Pp. 395.

Hooper's Physician's Vade Mecum. A Manual of the Principles and Practice of Physic. Pp. 338. William Wood & Co., New York.

The above works are members of the series of Standard Medical Authors published by Messrs. Wood & Co. Hooper's work appeared first over sixty years ago, but the present edition doubtless differs very widely indeed from that primitive volume. The one before us has been revised by Dr. William A. Guy and Dr. John Harley, who, we need not say, occupy the first rank among London practitioners. The book is therefore an excellent summary of theoretical and practical medicine.

The obstetrical work named above is the composition of a distinguished representative of this specialty in Paris. We do not perceive, however, that it is superior to some we could name by authors of our own. Those who have attended Prof. Pajot's lectures will be glad to find in the volume his obstetric tables, on which he used to lay so much stress.

——At the meeting of the Royal Academy of Medicine of Turin held the 8th of February, Professor Novaro presented a woman, aged forty-five, from whom he had removed, for carcinoma, the upper part of the œsophagus and the lower part of the pharynx, to the extent two inches and three-quarters. At the date of operation (September 3, 1883,) the patient could only swallow liquids with difficulty. She was able, when presented to the Academy, after the lapse of five months, to swallow solids. She was then in good health, and presented no traces of recurrence.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

DA COSTA'S
Medical Diagnosis

(LATEST EDITION)

FOR ONE DOLLAR!

This invaluable standard work by the eminent professor of practice in the Jefferson College, (published by J. B. Lippincott & Co., cloth, price $6.00), will be sent postpaid to any subscriber of the MEDICAL AND SURGICAL REPORTER, for *one dollar*, and the name of a new subscriber who agrees to pay for one year's subscription ($5.00) to the REPORTER within 30 days.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

THE SIGNIFICANCE OF SOME SYMPTOMS IN DISEASES OF CHILDREN.

Some diseases are very difficult to diagnosticate in children, and in some children still more than in others. There are many experienced physicians, making a specialty of children's diseases, who often recognize by a single symptom the malady from which their little patient suffers. It would not be wise to base prognosis and treatment upon such an intuitive diagnosis, but the knowledge of the importance of a single symptom enables us to examine the little sufferer more systematically and less at random; it saves us the trouble of having to hunt about long, as the one symptom instructs us where to look for the complaint.

It is with this object in view that we draw the attention of our readers to the interesting work of Dr. S. M. Politzer, recently published (*Deutsche Med. Z.*, May 19, 1884). Dr. P. was for a long number of years the Director of the "Public Hospital for Children," in Vienna, and as such has doubtless gained a great experience. He made the subject, which we mentioned above, a special study, and he considers mainly the following symptoms as having the greatest significance in establishing a diagnosis in diseases of children:

1. *If the cry of children has a decided nasal sound*, we should always look for a retro-pharyngeal abscess. Whenever the cry of a child has this peculiar nasal or guttural sound, we should never omit touching the posterior wall of the pharynx with our finger; if the abscess is present, we feel the tense, fluctuating swelling, so characteristic of retro-pharyngeal abscess.

2. *A noisy expiration, which is greatly prolonged* (10 *to* 15 *times*), *while inspiration is normal and no other disturbance of breathing, no dyspnœa whatever exists*, is a sure sign of chorea major, and the same can be said of a greatly prolonged, very loud, and forcible expiration, sounding like bellowing. This symptom of bellowing-(brüllend-roaring) expiration has a typical character; it may happen for many weeks daily at one and the same hour, recurring every seven to ten seconds, and it usually consists of a single prolonged and forced ex-

piration or of a single expiratory roar. For months sometimes this symptom is the only sign of chorea major. It is easily cured by large doses of quinine, but is very prone to relapse and to be accompanied by other symptoms of chorea major.

3. *The symptom of high-thoracic, continually sighing inspiration* indicates the beginning of debility and paralysis of the heart. Ere cyanosis or paleness of the face, a weak, thread-like pulse and coldness of the face, of the nose and of the extremities develop themselves—this symptom makes its appearance. Contrary to stenotic respiration, as observed in croup, pneumonia, and œdema of the glottis, this sighing inspiration is not characterized by forced contractions of the diaphragm, and is not of abnormal type, but is accompanied by a laborious rise and fall of the thorax and jugulum, and instead of a stenotic noise by continuous sighing and moaning. No matter how the paralysis of the heart may be produced—whether by so-called heart-poisons, as quinine, salicylic acid, pilocarpia and digitalis, or otherwise, the symptom just described is pathognomonic of the disease, and whenever met with, precautionary measures, to combat the threatening palsy of the heart, should be at once resorted to.

In some cases of acute fatty degeneration of the heart the same symptom has been observed.

4. *Expiration, decidedly diaphragmatic and accompanied by a whistling sound of high pitch*, denotes bronchial asthma. A similar symptom is also met with in croup; but here it is associated with stenotic, forcible inspiration. The same is observed in capillary bronchitis; but the noisy breathing through the nose, the rapid development of pulmonary emphysema, the sudden appearance and disappearance of intense dyspnœa and the fact of the latter and the whistling remitting during deep sleep, will prevent error.

5. *The existence of noticeable pauses between the end of each expiration and the beginning of the next inspiration* indicates severe catarrh of the larynx, and proves the absence of croup.

In consequence of the enormous aspiration of air in croup in- and expiration follow each other immediately, while in laryngeal catarrh a pause takes place between the two acts, as the physician can convince himself by bringing his ear near the mouth of the patient, or by carefully watching the diaphragm and the jugulum, both of which are at rest during a pause.

5. *So-called stridulous expiration*, if present at birth and continuing day and night with rare interruptions of ten or fifteen minutes' duration, and usually considered by anxious mothers, and the uninitiated, a dangerous and ominous symptom, has neither diagnostic, nor any other importance, being perfectly innocent, and generally ceasing of its own account after the lapse of a few months.

Then there are certain symptoms enabling us early to recognize various *diseases of the brain* in children.

1. *A remarkable drowsiness, not accompanied by fever or any other symptom, and continuing for a longer time* (1–3 *days*), often precedes basilar meningitis.

Vomiting, fixed pain in the head, even a slow, irregular pulse, have not the same great significance as this sleepiness, as they may also happen in other maladies. Certainly, stress must be laid upon the absence of fever, for many infectious diseases begin in children with a peculiar drowsiness, always associated, however, with more or less high fever.

2. *Prominent anterior fontanelle*, if decidedly reaching above the level of the surrounding parts, and if tense and of such a resistance as not to yield under pressure, proves the presence of an exudation within the cranium, or an increase of the contents of the latter, and is met with in purulent meningitis of the convexity, in cerebro-spinal meningitis of the epidemic variety, in acute, essential, and chronic hydrocephalus (here tense, but not necessarily very prominent), in great tumors, in echinococci, in acute œdema of the brain, and in intermeningeal apoplexy. In simple congestion, in acute hyperæmia of the brain, the anterior fontanelle always is soft and depressible. If the fontanelle is very prominent, almost cuneated and unyielding, without the least trace

of pulsation, the diagnosis of apoplexy of the new-born, and a large intermeningeal extravasation of blood can be made with certainty.

3. *Remarkably slow motion and long fixation of the bulbi with a vague look into vacancy, accompanied by a peculiar, slow opening and closing of the eyelids*, is a sign of beginning basilar meningitis.

Next, *peculiarities of the cry* of children aid us in the diagnosis.

1. *Violent, loud, penetrating crying, lasting two or three minutes, accompanied by great anxiety, as expressed in the face, and setting in almost typically* 1–1½ *hours after the child has fallen asleep*, is a symptom of nightmare, and easily cured by quinine, which in the dose of five to eight grains should be administered one or two hours before retiring.

2. *Periodical crying, lasting five to ten minutes and happening several times in the day, but occasionally only at night*, draws the attention to spasm of the bladder, if colic or dyspepsia is not present, and is cured by an emulsion of lycopodium with or without belladonna.

3. *Frequent crying during defœcation, dread of the act, and decided opposition of the child to going to stool*, indicate the existence of fissure of the anus. Constipation should be avoided in such cases and zinc-ointment with belladonna locally applied.

4. *Violent, very painful, and nearly continuous crying, with restless throwing of the head from side to side* on the pillow and frequent grasping of the head by the hands are generally indicative of otalgia and otitis media and externa.

5. *Crying, lasting days and weeks, greatly increased on touching or moving the extremities*, accompanied by continuous, enormous perspiration and fever denotes the presence of acute general rachitis, while the same symptom, without the sweating, but with decided emaciation, proves the existence of hereditary syphilis, and that the case is hopeless.

Of a great number of other symptoms we will mention but the following, as they are of more common occurrence and of greater importance.

When children are remarkably weak and little inclined to moving about after apparently innocent complaints of very short duration, *spinal infantile paralysis* may be expected. The least disturbance of hearing after acute diseases must be carefully inquired into, as it might be caused by *circumscribed meningitis* at the base of the fourth ventricle. Depression of psychical activity in small children after grave infectious diseases frequently forms the commencement of *acquired idiocy;* here strychnine has been proven by experience an invaluable remedy. Ossification of the bones of the cranium postponed longer than normal denotes beginning *rachitis*. An anxious, stiff action in walking, sitting, rising, etc., and pain expressed in the face of children, who do not yet walk, when they are lifted or laid down, are met with in the commencement of *spondylitis*. When children with a very large, closed cranium, for weeks vomit everything they eat, we have the proof that acute hydrocephalus is being added to the former chronic disease.

Though some of these symptoms are, indeed, very valuable, yet, we think, that many more of equal, if not greater, significance, could be detected in infants, were a physician with sufficient material at his disposal to take the necessary pains for observations of this kind.

THE CAUSE OF PNEUMONIA IN DWELLING-HOUSES.

Whatever we may think of the probable connection between animalculæ and infectious diseases, nobody can deny the fact, that certain special varieties of microzymes have been discovered in certain special zymotic maladies. Acute croupous lobar-pneumonia is one of these diseases, and a peculiar kind of micrococci has been demonstrated to be invariably present in this infectious complaint.

In the penitentiary at Amberg, near Regensburg, since 1857, a great many cases of acute pneumonia have taken place, and it seemed as if the disease at times assumed an epidemic character in that institution, while it continually was present as an endemic disorder. The last epidemic, happening from January to June, 1880, and during which 46 of 161 prisoners succumbed to the disease, induced the government to order a

careful investigation of the causes producing the malady. Dr. Emmerich received this commission. Careful researches soon enabled him to exclude occupation, diet, water, privies, and atmosphere as etiological elements. It is well known that between the outer brick-wall and the inner plaster covering of walls of rooms, there is a so-called "filling," a space usually filled out with laths and mortar. As nothing else seemed to open an explanation for the endemic, and frequently epidemic presence of pneumonia in the prison, E. resolved to examine carefully into the condition of this filling. Small particles taken from the layer below the board floor were powdered and spread over sterilized gelatine, prepared from meatwater-pepton (boullion). Within a very few days many and various kinds of micrococci-colonies commenced to develop themselves, and amongst them, those formed like the head of a nail, and of a milk-glass color, were predominant.

These cocci and diplococci were then separated from the others, and cultured by Koch's pure-culture process. The macroscopical, as well as the microscopical, appearance of these cultures exactly resembled the description given by Friedlander and Frobenius of the micrococci which these investigators had invariably found in the lungs of individuals having died with pneumonia. Blood-serum and potato-cultures gave the same result. It may also be interesting to state that besides these pneumonic micrococci, E. also discovered numerous bacilli of malignant œdema.

E. inoculated mice and guinea-pigs with the micrococci obtained by his pure-cultures from the cocci originally taken from the filling. He also caused other animals to inhale the micrococci. The blood, lungs and pleural exudation of the inoculated animals were filled with the microzymes, and of eight mice which had inhaled the micrococci, five succumbed to pneumonia.

The great importance of these researches will become apparent, if we remember that seven per cent. of all deaths are caused by acute pneumonia, and that tubercular phthisis is the only disease with a still greater mortality. By the introduction of suitable material for the filling of these "wall-and-floor interspaces," such a house-epidemic may in future be perhaps totally avoided. The material should be as little porous as possible, and be soaked in an aseptic solution.

CHOLERA.

Cholera is now raging in France, and a large number of deaths are daily reported from Marseilles, Toulon, and other French cities. Dr. Koch, the German scientist, who passed the last winter in India investigating this disease, is now at Toulon pursuing his researches, and it is reported in the daily press that he has discovered the same bacilli that have been already found by him in Egypt and in India. Owing to the commercial relations which Toulon has with the rest of the world, Dr. Koch is of the opinion that cholera will spread everywhere, hence should we be particularly careful to give it the cold shoulder, by using all means at our command to keep ourselves in good condition and by scrupulous cleanliness. It is very important that an apparently simple diarrhœa should not be neglected in cholera times.

Notes and Comments.

The New Hypnotic.

If paraldehyd should prove as reliable as the reports thus far published seem to promise, we have in it a really valuable hypnotic. The latest observer is Dr. E. Kurz, who in the *Centrlb. f. d. cl. Med.* (18, 1884), gives the result of his experiments with the remedy on twenty-four cases. With few exceptions the effect was favorable. Usually he administered the drug in the dose of three, sometimes four, grammes (gr. l. to gr. lxv.) and in watery solution. But in this manner taken the remedy has a very disagreeable taste, and Dr. Sutter, of Illenau, recommends rum as a medium. Paraldehyd is incorporated in sugar, so that in the form of troches, one of these contains sixteen grains. Three or four of them, according to Sutter, are then dissolved in rum and a few drops of essence of lemon added. Thus prepared, the disagreeable taste is utterly concealed, and the patients do not object to take it. Its administration in refracta dosi is not so reliable as the effect of a single large dose. In most

of K.'s twenty-four cases insomnia had been complained of for a long time, and had not yielded notwithstanding the use of narcotics.

We will mention some of the diseases in which it was employed by K. for sleeplessness:

1. Phthisis, after repeated administration of paraldehyd, prompt effect.

2. Insomnia, with great restlessness after several days of railroad travel; perfectly quiet sleep restored after first dose.

3. Large ulcerated carcinoma of the mamma; after the pains had been subdued by hypodermic injections of morphia, sleep was induced by paraldehyd. Morphia and cannabis indica had not been effectful, and chloral had caused only excitement.

4. Insomnia, after violent psychical excitement; chloral had here also caused sleep, but been followed by severe headache; effect of paraldehyd instantaneous.

5. Mitral insufficiency with severe dyspnœa; neither morphia, cannabis, nor chloral caused sleep; paraldehyd did so, but partially.

6. Insomnia after typhus; morphia produced excitement; cannabis was useless; paraldehyd acted promptly.

7. Acute melancholy. Prompt effect.

8. Insomnia in childhood. Paraldehyd caused a quiet slumber.

9. Intra-orbital neuralgia. Paraldehyd induced sleep, but the effect of cannabis was still better.

The same was noticed in a 10th case, where chronic otitis had produced the sleeplessness.

Of the twenty-four cases but four evinced no or but partial hypnotic effects from the remedy. The opposite effect, excitation, as often observed of morphia and of cannabis, was not seen in any case in which paraldehyd had been employed. Sleep generally set in within thirty minutes, and lasted from five to seven hours. Even in the few cases in which no hypnotic effect ensued, the patients admitted having felt much quieter after the paraldehyd; pulse became slower and arterial tension lessened, if previously increased; disagreeable effects were never noticed.

The Pathology of Alcoholism.

It is of interest, as showing how wide-spread is the bad influence of alcohol, that we should note that Dr. Chambers exhibited to the Baltimore Medical Association, April 14, 1884, specimens obtained from the autopsy of a painter, æt. 52, who had been an excessive whisky-drinker all his life, and who had been sick seven months before death with gastric symptoms. There was no œdema at any time except a little puffiness under the eyes. The heart was hypertrophied. The urine contained a minute trace of albumen; death took place quietly without coma or convulsions. The liver and spleen seemed contracted. The former contained cicatrices, and the left lobe was almost gone. The kidneys were also contracted. The capsule of the spleen was five or six times its ordinary thickness (peri-splenitis), and the organ was very hard. The pancreas is a mere shred of connective tissue; the ducts feel like cartilage. There were also evidences of pericarditis. The stomach was contracted and very vascular, notwithstanding the specimens had been in alcohol several days. There was some doubt as to what the patient died of. Four or five organs were diseased sufficiently to cause death. The liver looks a little suspicious as to specific disease, but other signs are wanting. It is not a typical hob-nailed liver. The lungs are healthy, except a little emphysema. The death certificate assigned Bright's disease as the cause of death.

Diphtheria and Inflammation of Joints.

A young military cadet, æt. 15, was attacked on the sixth day of diphtheria by inflammation of both knee-joints, which in a second case, that of a cadet æt. 13 beginning on the eighth day, most of the larger joints and the pericardium became excessively inflamed. In both cases, though in the second a mild relapse took place, a perfect recovery ensued after the administration of salicylic acid. The patients were in charge of Dr. Panto (*Berl. Klin. Woch.*, 45, 1884), who, not adopting the theory of Senator, Vohsen, *et al.*, believes that this affection of the joints is caused by direct and repeated impression of the diphtheritic poison, which reaches the diseased tissues from from the blood by aid of the lymphatic system. The character of these joint affections has not yet been clearly determined, and it has been called rheumatic simply in contradiction of those acute purulent inflammations with which we meet in cases of pyæmic arthritis. We find the same in scarlatina, and here also it would be wrong to give them the name of pyæmia, while a purulent inflammation has never been observed. They are nothing but inflammation of serous membranes, due to a specific poison.

Papilloma of the Male Bladder.

Mr. S. Peake reports a case in the *Lancet*, April 26, 1884, wherein Mr. Henry Morris operated by

removing the growth through a perineal incision after having ligatured the base of the tumor; and he suggests that he considers the case of great interest, chiefly as suggesting the occasional advantage, when dealing with bladder tumors, of separating the stages of the operation—namely, of opening the bladder and awaiting for the expulsive efforts of the contracted bladder to expel the free extremity of the growth through the wound, then after a day or two to complete the removal in the manner adopted in this case. Such a course, when practicable, is more safe and more accurate than crushing off the growth with the lithotrite or Thompson's forceps. When the tumor is of the papillomatous character, it is probable that in no inconsiderable proportion of cases its expulsion may be looked for. In the female bladder the free ends of papillomatous growths are often floated outwards to and beyond the external urinary meatus. The previous formation and removal of a prostatic calculus supports the theory referred to by Sir Henry Thompson, "that papilloma may sometimes arise from local sources of irritation affecting a mucous membrane."

Substitute for Nitrite of Amyl Capsules.

Recognizing that it must often happen to medical men, espscially those in the country, that just when they want these capsules in an urgent case they find they are without them, and while the physician might administer it from the bottle, it would be dangerous to leave the bottle around, Dr. R. L. Batterbury suggests this plan in the *Brit. Med. Jour.*, May 3, 1884: Some small, wide-mouthed bottles should be obtained with closely-fitting corks, and into each bottle a little cotton-wool should be placed. All that is necessary is to drop the required dose into the bottle, cork it tightly, and invert it. In this inverted position the nitrite of amyl will retain its properties unimpaired for a considerable time, for some months at least, and can be used by simply removing the cork and applying the bottle to the nose of the patient.

Œdema Glottidis from Syphilitic Ulcer of the Larynx.

One of the numerous phases which this affection may present is offered to us by Dr. R. B. Jessup in the *N. Y. Med. Jour.*, May 17, 1884, where œdema glottidis was caused by it.

A diagnosis of œdema glottidis was made when he first came into the hospital, but the cause of it could not be made out. The ulcer was, in all probability, syphilitic in its nature, for the scars of old ulcers were found on the leg, and his nose was sunken and deformed. That there was œdema present, was not doubted by any one who saw him before the tracheotomy was done, and even at the laryngoscopic examination the parts were still somewhat œdematous and swollen. The caseous matter seen could not have produced the intense dyspnœa in itself, for it was not tenacious in its consistence, and could easily be wiped away. Authorities agree that the œdema of syphilitic ulcer of the larynx differs from that of tuberculous laryngitis in that it is more gradual, whereas the œdema of tuberculous laryngitis is quite abrupt in its development. After tracheotomy the patient rallied for awhile, but he soon sank and died.

Dilatation for Fissure of the Anus.

The method is discussed at some length in the *Revue de Thérap.* for February, 1884. Gradual dilatation is not recommended by the authors, but forced and rapid dilatation is said to give excellent results. The index fingers may be used for the purpose, but the thumbs are generally too short. Mollière, Verneuil, Trélut, and others, make use of expanding specula of various forms. An enema must be given on the day before the operation, and the administration of an anæsthetic is generally advisable. The dilatation is known to have been sufficient when two fingers can be introduced together into the rectum without feeling of resistance. The patient can resume his occupation after two days. Incontinence of fæces does not occur after rapid dilatation.

Painless Escharotics.

From the *St. Louis Druggist* we learn that Esmarch's painless caustic powder, for the removal of warts, tumors, etc., is composed of:

℞.	Arsenious acid	part 1
	Sulphate of morphia	" 1
	Calomel	" 8
	Pulv. gum arabic	" 48

This is to be sprinkled on the cuticle daily. The surface should be denuded either with the knife or a blister. Canquoin's paste, for the same purpose, is made, according to M. Charles, by the following formula:

℞.	Chloride of zinc, fused	parts 10
	Alcohol, 60 deg.	" 2
	Wheat flour	" 15

Rub the zinc chloride to a fine powder, add the alcohol, rub again and incorporate the flower strongly pressing with the pestle. As soon as

the paste is homogeneous, spread with a roller or bottle into sheets about one-eighth of an inch thick, and after a few hours put into a well-corked bottle.

Latour's nitro-chloride of zinc paste, a most excellent escharotic, is made by dissolving 50 parts of chloride of zinc and 100 parts of nitrate of zinc in 80 parts of water. The solution is made by the aid of heat. When it cools, add to each 100 parts of the fluid, 75 parts of wheat flour, and incorporate as in Canquoin's paste.

Death from an Injection of Carbolic Acid.

A valuable warning is sounded by a case before the Calcutta Criminal Sessions in April, when Dr. Upendra Krishna Dutt was found guilty of causing death by a rash and negligent act, and was fined 500 rupees. The convicted person, who was a young native medical practitioner, administered an enema of carbolic acid to the child of his cousin for the cure of dysentery or worms. Two hundred drops of Calvert's No. 2 carbolic acid were injected; and there could be no doubt that, whatever was the nature of the child's illness, the carbolic enema had caused the death, which occurred in a few hours. There was collapse almost immediately after the injection of the acid, which was dissolved in water.

Injections of Corrosive Sublimate Solutions into the Inguinal Glands and in the Spleen in Syphilis.

Dr. Hugo Engel has been making these injections, and as a result of his experience, he tells us, in the *Medical Times*, June 14, 1884, that he thinks he is entitled to say that there is some reason why, in cases of enlargement of an inguinal gland, following an indurated primary sore, hypodermic injections of corrosive sublimate should be tried, and in cases where there has already been an indication of further constitutional affection, as roseola, and where no special accidental conditions (as above enumerated) contra-indicate their employment, the same solutions should be injected into the parenchyma of the spleen, and in both cases be continued until the first warning symptoms foreshadow the approaching mercurial stomatitis.

Insanity and Cardiac Disease.

In connection with the paper on this subject, read before the Pennsylvania State Medical Society by Dr. Alice Bennett, and published in our columns, it will be interesting to note that Dr. James G. Kiernan thus concludes a paper in the *American Journal of Neurology and Psychiatry:*

Taking all narrated cases into account, it would seem justifiable to conclude:

1. That cardiac disease produces psychical symptoms; depressions and hallucinations, as well as delusions.

2. That cardiac disease may modify coëxisting insanity.

3. That insanity may produce cardiac symptoms.

Internal Urethrotomy for Urethral Stricture.

That distinguished veteran, Sir Henry Thompson, tells us in the *Brit. Med. Jour.*, June 14, 1884, that according to his experience internal urethrotomy, completely performed, should be resorted to as the best and safest treatment of stricture, as soon as the easy use of the bougie fails to maintain the urethra patent, or to allay signs of irritation in the bladder arising from obstructed urethra. It is the best means not only for relieving urethral obstruction and its painful symptoms, but for ensuring the future sound condition of the organs which lie behind it.

A New Treatment of Epithelial Cancer.

Experiments now in progress, under the supervision of Dr. J. E. Garretson, at the Oral Hospital of this city, show a wonderful curative value in the treatment of epithelial cancer with the use of epiderm secured from the horse by means of a curry-comb, the treatment being nothing more complex than keeping a sore continuously covered with the ash-colored powder thus obtained. The horses are to be washed over night and curried with a new curry-comb in the morning. After picking out the hairs the powder is ready for use. Where horse epiderm is not to be obtained, the scales may be scraped by means of a knife-blade from the human arm or leg.

Treatment of Pelvic Rachialgia.

For this painful affection Dr. G. Liebbman says in the *Boston M. and S. Jour.*, that he considers the best treatment to be the administration of drachm doses of sulphate of magnesia before breakfast three or four times a week, cold ablutions of the lumbar and hypogastric regions, and moderate bodily exercise, as gymnastics, horseback riding, billiard-playing, and so on. Furthermore, he finds celibacy on the one hand, and excesses in venery on the other injurious, but a very moderate and judicious performance of the sexual functions beneficial.

Iridin in the Vomiting of Pregnancy.

Being led to try it by the allusion of Dr. Matthews Duncan to the probable influence of the liver in causing the vomiting of pregnancy, Dr. Berry Hart, in the *Edinburgh Clin. and Path. Jour.*, recommends the use of two grains of iridin in the form of a pill to be taken at night, and to be followed in the morning by a draught of Friedrichshall water, a teaspoonful of Carlsbad salts, or a doubly strong Seidlitz powder. He states that out of nine cases where this treatment was tried, eight were cured.

CORRESPONDENCE.

A Case of Spinal Bifida in the Upper Cervical Region.

EDS. MED. AND SURG. REPORTER :—

On June 14, 1884, I delivered Mrs. —— of a pair of twins—a boy and girl. The girl had spina bifida in the *upper cervical region*, involving the first and second vertebræ. It was as large as a good-sized hickory nut, and is gradually increasing in size. The child, so far, has appeared well, with the exception of being more fretful than the other.

A. O. STROUT, M. D.

Parkersburg, Iowa, June 23, 1884.

Picrate of Ammonia in Whooping-Cough.

EDS. MED. AND SURGICAL REPORTER :

Dr. Z. P. Dellenbaugh, formerly of Philadelphia, now of this city, has been for some time using picrate of ammonia in whooping-cough. At his suggestion I have employed it, and can corroborate what he claims for it, viz., a speedy mitigation in both the number and severity of the paroxysms. His formula for a child of four years is :

℞. Ammon. picratis, gr. ij. @ iij.
Ammon. muriat.,
Ex. glycyrrhyz, āā ʒj.
Aquæ ad., fl. ℥iij.
S.—Fl. ʒj. every three hours.

I have been less disappointed in this treatment than in any I have as yet tried. It would seem worth a thorough trial by the profession.

L. B. TUCKERMAN.

Cleveland, O., June 19, 1884.

Chloroform Not a Tæniafuge.

EDS. MED. AND SURG. REPORTER :—

In your issue of April 26 a physician in Kentucky stated that he had for some years past treated his cases of tape-worm with invariable success by administering, after a day's fasting, one-drachm doses of chloroform in one and one-half ounces of castor oil, sometimes adding a little male fern, but had been equally successful without the male fern. I was much pleased that at last we had found a remedy which would invariably bring the head of the worm; and soon after, having a patient passing joints, I made him fast twenty-four hours, and then take the oil and chloroform. The patient did as directed, only more so. After the dose had ceased purging, and he had failed to find his worm, he at once repeated the dose on his own responsibility, but did not so much as get a single segment. I told him to wait and see if he passed any more pieces before renewing treatment. In a few days he was passing them again, and with two one-drachm doses of kamella expelled about fifteen feet of the animal, including the neck close to the head, so that it is unlikely it will give any more trouble. Of course, "one swallow don't make a summer," but the fact that this patient took two doses of the remedy in quick succession without any result whatever, except a tremendous purging, does not lead me to place much confidence in it; and my object in writing this is simply to caution against its use until we get more decided testimony as to its efficacy.

WILLIS J. BEACH, M. D.

Litchfield, Conn., June 27, 1884.

Malignant Pustule.

Open Letter for Medical and Surgical Reporter.

W. S. JANNEY, M. D., PHILADELPHIA—*Dear Doctor:* In the *New York Med. Jour.* of the 7th inst., just received, I find a report of four cases by you in the proceedings of the Philadelphia County Medical Society, which are designated as "Malignant Pustule." As my residence abroad for quite a number of years gave me an opportunity for a practical knowledge of this affection, in contradistinction from the furuncular development known ordinarily as carbuncle and technically as anthrax, I would invite your attention, as well as that of the colleagues who engaged in the discussion, to my elaborate paper on this subject in the September number of *Gaillard's Medical Journal* for 1881. It is entitled "The Distinguishing Features of Malignant Pustule and Anthrax," and sets forth that "The most general characteristic difference between anthrax and malignant pustule is the quality of the former in being a localized effect of a constitutional derangement, while the latter is the local origin of a general disorder. Anthrax is a consequence, while malignant pustule is the origin or commencement of the disturbance of the animal economy." "Should the primary vesicle of malignant pustule be allowed to take its course, there soon extends a disintegration of tissues to some distance around and beneath the spot, and this disorganization affects the nerves and small ramifications of the blood-vessels in a way to carry a deleterious impression to the entire frame, and especially to the brain." "It is noted as a remarkable feature that the sensibility, even in the primary vesicle, is so entirely lost as to admit of burning with red-hot iron thrust into the cavity without giving any pain." "No case suspected of being malignant pustule should be allowed to run on and develop this dreadfully-destructive type of disease, but should be promptly obliterated by the use of the thermo-cautery, until the action of the red-hot iron becomes actually felt upon reaching the solid tissues which surround the diseased part." "A stimulating antiseptic internal treatment should accompany these measures of local correction."

It being impracticable to communicate any definite conception of the scope of the paper by meagre extracts, you are referred to the essay for my views, with the conviction that much of the uncertainty as to diagnosis, pathology, and treatment, should be dissipated by a correct appreciation of the facts afforded by my personal observation.

Lobelia Inflata.

Eds. Med. and Surg. Reporter:

I am confident no one who has used lobelia properly, *i. e.*, in small doses frequently repeated, would like to be deprived of its valuable properties in the treatment of angina pectoris, dyspnœa attendant upon cardiac oppression, or those cardiac disturbances of a reflex origin.

The following case from my pocket record of a recent date will illustrate the brilliant action, in a case of pre-cardial oppression in a rheumatic lady, 40 years, large and fat, weighing 200 pounds. Was attacked at 10 o'clock a. m. with intense pain in the precardial region, attributed to indigestion. The family attempted to relieve by mustard emetic, cataplasms, and the general routine practice of antiacids, carminatives, stimulants, and warm applications. I arrived at four o'clock, found her sitting in bed, with a horror-stricken expression, complaining of great pain in region of heart and under sternum, the surface bathed in a cold perspiration, with a sick nauseous stomach, the radial pulse scarcely perceptible, the heart's action weak, irregular, and thrilling or shivering, the chest wall fixed, the breathing labored and quickened, with a gasping cry, "I shall die doctor, if not relieved at once! I shall die!! I want breath!!!" I thought of lobelia and nitrite of amyl; had no lobelia, but crushed a part of five gtt. of amyl on a handkerchief, and applied to nose, which afforded some relief, but intensified the nausea and pain under breastbone, with a greatly intensified thrilling or shivering of the heart's beat. I went for the tr. of sem. lobelia, which I administered in gtts. xx., and again went to prepare a dose of chloral, but on entering her presence found the symptoms better, and again repeated tr. lobelia gtt. xx., which in half an hour had so far removed the alarming symptoms that I did not give the chloral, but ordering a flannel wrung out of warm whiskey and water placed over heart, and to be renewed if necessary, left to call again at 9.30 a. m., when I found her asleep, breathing superficially and rather faster than normal, but the pain and oppression all gone, with small blisters over heart, repeated by moving from place to place around and over this organ. With iodide, bromide, and salycilate of soda and potass., she came from under the heart complications, but still with the rheumatism in right shoulder and arm, so much so as to prevent raising hand to head.

Could repeat numbers of such heart troubles, with quite as many of retarded labor, where the action of lobelia was quite as brilliant in the relief of similar action of the womb as in this neurosis of the heart. Lobelia may be ranked as a vital stimulant to the great sympathetic nervous system, and whenever it is desirable to give tone and energy to any particular organ that had been overpowered by disease, or acted upon reflectively so far as to interfere with normal action, the profession will be rewarded by the most brilliant results in giving lobelia. With children it is very potent; never having seen any article tone up so wonderfully irregular nervous action in children as lobelia, given in fractional gtt. doses, every ten or fifteen minutes, with a proper after-treatment, as it is the remedy for the emergency only.

It is hoped the profession will lay aside all prejudice, if any exist, and investigate the action of lobelia, not as an emetic, but a vital stimulant, as I am confident of what I state; and while there may be cases or idiosyncrasies not tolerant of its effects in large irritant doses as an emetic, yet I assert there are no cases where a vital stimulant is demanded, that lobelia will not act promptly and brilliantly, if given in small doses, frequently repeated.

H. J. Smith, M. D.

Blackshear, Ga., May 13, 1884.

When to Use and When Not to Use the Lancet.

Eds. Med. and Surg. Reporter:—

I am glad my hastily-written article of a month or so ago has met with the approbation of at least one member of the profession—Dr. De Armond—and if the ideas there set forth could in any way benefit any young practitioner I should feel highly gratified. In order to more fully elucidate my position, if you will allow me space, I will give a case or two in point.

Some years ago my brother, a minister belonging to the Pittsburgh M. E. Conference, was called on, in the course of his ministerial duties, to immerse some parties in early spring—March—and the water being very cold, and becoming exhausted from the labor, he contracted a severe cold, which resulted in acute nephritis, for the treatment of which he placed himself under my care. Getting better, as he did, he returned to his work too soon, against my wishes, and in a short time he returned to me infinitely worse than ever.

He had not been at my house more than an hour or two, when as I was preparing to apply some cups to the region of the kidneys, he suddenly passed into a violent convulsion, which was horrible to see, and which I diagnosed as the result of uræmic blood-poisoning. The bystanders thought he was dying; and so he was, if relief had not come speedily. I immediately plunged his feet into a bucket of hot water—I don't know how hot—and opened a vein on the top of the foot, and allowed the blood to run until he fainted, when consciousness returned. He had no more convulsions, but it was six months or more before he was able to go to his appointment, and he never became quite so well as before he contracted the cold.

Now, this was a case in which bleeding was absolutely the only remedy, in my opinion. I can think of no medicine that would reach such a case. What was done had to be done quickly. Hypodermics would probably have relieved the convulsion, but would not have relieved the brain-pressure. Therefore, I would advise my younger brethren, and older ones too, for that matter, to always have the lancet within reach, and when

the necessity arises for its use, use it boldly and effectually.

A few weeks ago, as I was passing down the street in our town, a vigorous, robust man, of some forty years, drove up to his door and called to me, and said he was so chilly he could hardly keep from freezing, had headache, pains in his bones, back, etc. His boy went with me to my office, and I sent him:

℞. Spts. vin. frumenti,
Aromatic spts. am., āā ℥ij.
Quinia sulph., grs. xx. M.

Of this, a tablespoonful was to be taken every hour until relieved, with three or four comp. cath. pills at bedtime. I was called away, and did not see my patient until next afternoon, when he was found sitting by a red-hot stove, complaining of a terrible pain in his right lung, extending to the pleural region. His pulse was full, rapid, strong; headache; slight dulness in lower lobe of lung on percussion; breathing painful. He was scared, as he had had a bad attack of pleuro-pneumonia some years before, and for which I treated him *without* bleeding. He wanted to be bled; I did not think it necessary, besides, my lancet was at my office; but I had a large, thick mustard poultice applied to his chest—all over the painful parts—put his feet in hot water, gave him stimulants, and next day he was on the street as usual. In such a case as this, I presume, Dr. Corson would have taken, from as robust a man as my patient, 24 or 32 ounces of blood, and would have advertised how he treated another case of pneumonia by his own peculiar method. Of course, after losing a pint or a quart of blood, the man would have been two or three days getting about; but all the same, the old doctor would have laid claim to an immediate cure, and blood-letting, according to his theory, would have been the only remedy that would have effected a cure. Now, here I have presented two cases, occurring in actual practice, the one in which bleeding was the *sine qua non*, the other in which it was not only unnecessary, but when its employment would have been exceedingly foolish and detrimental. Supposing I had been a bleeder, and according to the request of my patient, I had bled him freely? Of course he would have gotten well, for nothing serious ailed him, and I could have boasted of how quickly I aborted a severe case of pneumonia. On the other hand, since I do not believe in indiscriminate bleeding, I only record a case such as every practitioner has seen hundreds of times. Such, I verily believe, are the kind of cases of pneumonia which are cured so easily by the bloodletters; for in genuine inflammation of the lung, with the accompanying fever and prostration, no treatment—be it depletion, stimulants, or whatever—can cure it in as short a time as the bleeders claim.

Wm. F. Mitchell.

Addison, Pa., June 11, 1884.

News and Miscellany.

Indiana State Medical Society.

At the annual meeting held in Indianapolis, June 10, 11, 12, 1884, the following papers were read: "Angel-Wing Deformity," by Dr. G. W. H. Kemper. "Adenia, or Hodgkin's Disease," by Dr. L. B. Woollen. "Four Cases of Ovariotomy," by Dr. Joseph Eastman. "Post-Partum Hemorrhage," by Dr. J. F. Hibberd. "A Question in State Medicine," by Dr. S. E. Munford. "Post-Partum Intra-Uterine Injections of Carbolic Acid," by Dr. H. V. Sweringen. "Puerperal Pyemia," by Dr. W. H. Myers. "Malpractice Suits; Can their Frequency be Lessened?" by Dr. J. R. Weist. "Asthenopia," by Dr. J. L. Thompson. "Small Pox and the Pest House," by Dr. Theodore L. Wagner. "The Treatment of Fractures of the Leg," by Dr. J. W. Marsee. "Antiseptic Treatment of Gunshot Wounds," by Dr. H. T. Raymond. "Two Cases of Foreign Bodies in the Trachea," by Dr. B. Wallace. "Intra-ocular Tumors," by Dr. T. J. Dills. "Race Poison," by Dr. J. S. Arwine.

Officers for the ensuing pear:

President—J. H. Woodburn, M. D., of Indianapolis.

Vice President—James A. Grigg, M. D., of Fort Wayne.

Secretary—E. A. Elder, M. D., of Indianapolis.

Assistant Secretary—W. H. Lopp, M. D., of Columbus.

Treasurer—G. W. H. Kemper, M. D., of Muncie.

Michigan State Medical Society.

At the meeting held at Grand Rapids, June 11 and 12, the following papers were read: "Expert Testimony and Compensation," by Dr. Samuel P. Duffield. "The Dry Treatment of Chronic Suppurative Inflamation of the Middle Ear," by Dr. C. J. Lundy. "Developments of Medical History, Science, and Art," by Dr. A. F. Whelan. "Large Doses of Turpentine in the Treatment of Diphtheria," by Dr. C. George. "Exploration of the Male Urethra," by Dr. H. O. Walker. "Prostatic Hypertrophy and Urinary Obstruction; Its Treatment without Catherization," by Dr. A. B. Palmer. "Sterility in Women," by Dr. J. H. Carstens. Nichols. "Granulated Lids," by Dr. Eugene Smith. "Chronic Catarrhal Otitis," by Dr. R. J. Kirkland. "Therapeutics of Dysmenorrhœa," by Dr. A. R. Smart. "Uterine Displacements," by Dr. Wade.

Officers for ensuing year:

Vice Presidents—Drs. J. Perkins, of Owosso; J. M. Cook, of Muskegon; Gordon Chittock, of Jackson; Carl Brumme, of Detroit.

Secretary—Dr. Geo. E. Ranney, of Lansing.

Treasurer—Dr. A. R. Smart, of Hudson.

Rhode Island Medical Society.

Officers for the ensuing year:

President—Dr. Oliver C. Wiggin.

First Vice President—Dr. Horace G. Miller.

Second Vice President—Dr. John W. Sawyer.

Recording Secretary—Dr. George D. Hersey.

Corresponding Secretary—Dr. Edward M. Harris.

Treasurer—Dr. Charles H. Leonard.

Censors—Drs. Ariel Ballou, J. H. Eldredge, J.

W. C. Ely, G. P. Baker, S. S. Keene, Benjamin Greene, E. T. Caswell, and G. Kingman.

Minnesota State Medical Society.

Officers for ensuing year:

President—Dr. J. B. McGaughey, of Winona.

Vice Presidents—Drs. F. A. Dunsmoor, of Minneapolis; W. H. Pratt, of Stillwater; and C. A. Wheaton, of St. Paul.

Treasurer—Dr. S. B. Sheardown, of Stockton.

Recording Secretary—Dr. C. H. Boardman, of St. Paul.

Corresponding Secretary—Dr. A. F. Ritchie, of Duluth.

Censors (for three years)—Drs. J. C. Rhodes and V. Smith.

Colorado State Medical Society.

Officers for the ensuing year:

President—Dr. Hause, of Greeley.

Vice Presidents—Drs. Solly, of Colorado Springs; Rogers, of Denver; and Earhart, of Boulder.

Recording Secretary—Dr. S. A. Fisk.

The society will meet next year at Denver.

Items.

—The parenchymatous injection of the ergotine of Yvon in goitre is recommended by Dr. Bauwens, of Alost.

—Salicylate of sodium, when administered in large and repeated doses, has been followed by metro-neuralgia.

—It is related of Sylvius, that he compelled his patients to drink from one hundred and fifty to two hundred cups of tea every day.

—In the *Brit. Med. Jour.*, May 10, 1884, Dr. Henry Sewell reports a case of spasm of the muscles of the face and cataract due to dental irritation.

—A case of aphasia, with integrity of the third left frontal convolution, but with damage of the subjacent white matter, is recorded in the *Gaz. Médicale de Paris.*

—Pains in the course of the ulnar nerve have been noticed by M. Treille to accompany conditions of nervous dyspepsia. They belong to the phenomena of "exterioration."

—The syphilitic negro, says Dr. Henry R. Carter, has oftener enlarged and suppurating glands, rheumatic pains, and synovial inflamations. He less rarely has mucous patches, nodes, and caries.

—The sulpho-carbolate of sodium, in thirty-grain doses given after meals, is recommended in flatulent dyspepsia. Also in ten-grain doses for nausea and vomiting, particularly in pregnancy.

—Dr. M. Heath, of London, thinks the separation of the fragments of the patella due not to muscular action, but to presence of fluid in the joint. He aspirates when necessary, but prefers to put the knee at once in a plaster splint.

—A young lady died recently at Cherbourg in great agony after having taken an injection of aconitia prepared by a pharmacist in mistake for pilocarpine. The druggist discovered his error shortly after it was committed and ran to the lady's house to warn her, but arrived just in time to see her expire.

—Dr. J. Feld, of Kansas City, reports in *The Clinique* that in six cases of adherent placenta he has saved the woman by pumping cold water through the umbilical cord. In one case the patient was in convulsions when the after-birth came away.

—In a short preliminary note in the *Vratch*, 1883, No. 40, p. 625, Prof. N. V. Sorokin, of Kazan, states that he has discovered a new polymorphic micro-organism, which is invariably met in cases of follicular tonsillitis. The author proposes to name this micro-organism, leptothrix anginæ.

—Dr. Hammond says he knows of no better tonic for the sexual organs in impotence in the male than the following prescription:

℞.—Strychniæ sulph.,	gr. 1,
Acidi hypophosph. dil.,	℥ 1.

Mix.

Ten drops of the solution three times a day before meals, in a teaspoonful of the fluid extract of coca. The medicine should not be taken immediately before retiring, as it is apt to cause seminal emissions.

MARRIAGES.

BELDEN—ANDREWS.—On Wednesday, June 11, 1884, at St. Michael's church, Litchfield, Conn., by the Rev. Storrs O. Seymour, assisted by the Rev. L. P. Bissell, Dr. Charles Ogilvie Belden, and Katherine Goodwin, daughter of Judge Charles B. Andrews, both of Litchfield.

BELLMAN—WITHINGTON.—On Thursday, June 5, 1884, at the residence of the bride's mother, Kingston, N. J., by Dr. Thomas S. Hastings, of New York, Edmund Roberts Bellman, of Newark, N. J., and Marea Roshove, daughter of the late I. Chandler Withington.

BROWN—STRONG.—In New York city, on Wednesday, June 4, 1884, by the Rev. T. M. Peters, D D., Dr. F. Tilden Brown and Mary C. Strong, daughter of the late William R. Renwick.

CURTIS—ALLEN.—On Thursday, June 19, 1884, at Grace church, Brooklyn Heights, by the rector, the Rev. Wm. A. Snively, D. D., assisted by the Rev. Henry T. Scudder, Dr. H. Holbrook Curtis, of New York city, and Josephine, daughter of the late Hugh Allen, esq., of Brooklyn.

FERRIS—HILLS.—On Thursday, June 19, 1884, at St. Peter's church, Delaware, Ohio, by the Rev. Wm. Bower, G. Newton Ferris, M. D., of Flatbush, L. I., and Katharine May, daughter of Chauncey Hills, esq.

LEAKE—HOUSTON.—On June 4, 1884, by Rev. Thomas Murphy, D. D., E. F. Leake, M. D.. and Mary J., daughter of the late Churchill Houston, all of Frankford, Philadelphia.

WHITE—TWEEDY.—At St. James church, Danbury, Conn., on Thursday, June 12, 1884, by the Rev. Mr. Hall, rector of the parish, Granville M. White, M. D., and Laura Dunham Tweedy, both of Danbury.

DEATHS.

AGNEW.—June 18, 1884, Sarah B., wife of Dr. J. P. Agnew, and daughter of the late Stacy Brown, in the 45th year of her age.

BUTLER.—In Louisville, Ky., on June 11, 1884, Dr. J. Russell Butler.

HOUSTON.—In Iuka, Miss., June 8, 1884, Dr. Pugh Houston, in the 82d year of his age.

MOFFET.—On June 18, 1884, Dr. John Moffet, in the 54th year of his age.

SHELTON.—In New York, Charles J. Shelton, son of the late Dr. John D. Shelton, of Jamaica, L. I., aged 25 years.

WARD.—At Bristol, Pa., on May 31, 1884, Emma Jane, wife of John Ward, M. D., and daughter of the late Edward W. Mumford, deceased, aged 40 years.

SOME REMARKS ON PUERPERAL FEVER FROM A COUNTRY PHYSICIAN'S STANDPOINT.

BY W. H. HEPBURN, M. D.,

Of Freehold, New Jersey.

Not with the expectation of adding to the facts we have so lately had placed before us (by the renowned New York gynæcologists and others), but to make some statements in regard to the way the disease has impressed one who not only had an epidemic of this disease in his own field, but was, at the time of this epidemic, associated with three other physicians, the oldest of whom was a practitioner of thirty years' standing, having an immense experience in general practice, and especially in obstetrics, and so puerperal diseases; and, best of all, was a man of undoubted ability. These circumstances I relate only to impress the truth that, though a young M. D., I have had unusual opportunities to learn by sad experiences the errors into which one can fall, and also, by experiences and teachings of one whom, as a practitioner, I admire and trust, many very useful lessons. I do not know where, outside a hospital, one would be so likely to see so many cases—if an epidemic of this disease once started—than in the coal regions, where the births are numerous, the houses usually very poor, and the towns crowded.

One, also, has every opportunity to see how disease can be treated when city hospitals, appliances, etc., are not at hand. So much sarcasm has been displayed, and so much cynicism exists in regard to the treatment of this and some other diseases, that to show from what standpoint I base my use of medicines, I will quote from an article I wrote on "Inflammation:"

"Let us start with the fact deeply impressed upon us that we have no specifics. That truth impressed upon some persons would seem to them to prove that the practice of medicine is an utter failure. To us it shows how necessary it is that the profession contain men who have power of keen observation, cool heads, self-confidence, and honesty of purpose.

"Do we ask of a pilot, in order that he be fitted for his duties, that, when the storm rages and the vessel is tossed about on the waves as if a block of wood—I say, do we ask of the pilot that he be able to say, 'peace, be still,' and there shall be a great calm. Only one being was ever able to do that. What we require is that he know well his course and how to conduct his vessel—if human power can—through the storm. So we can, with justice, demand of the physician; and as I have watched by the bedside of a struggling life, I have often thought how much more our responsibility is than if we could give a drug and see health immediately return. Shall I stimulate or shall I depress? What does this pulse indicate? How can I best subdue this inflammation?"

These, and kindred questions, present themselves to every intelligent physician, and on the correct answering of them often depends a life. But to return to our subject.

City physicians have so many conveniences, and are surrounded by all the latest improvements, which they can secure at a moment's notice, also

trained nurses fitted for any emergency during the doctor's absence, that they but little realize to what straits we, who live in the country and smaller places, are often put. And the treatment they demand is often utterly beyond the country brother's resources to follow out. The result might be that on reading of the successful treatment of some disease by a city physician, and knowing that neither time or appliances are at his disposal, I say, it might be that our country brother should become discouraged or dispirited, because he could not, as he imagined, do justice to his patients.

Let me illustrate: In an article on treatment of puerperal fever, by one of the leading specialists on women's diseases, the following, among others, rules were given: "The frequency of the injections (intra-uterine) should vary according to the severity of the disease. In mild cases, one every five hours is sufficient. In others, injections should be repeated every *three hours*, and in bad cases *every hour*." Now, all who know anything about country physicians, know that two visits a day demand a heavy strain upon them, how then could he observe these rules? Nevertheless, I know it is a recognized fact, that few people receive better, more faithful and conscientious attendance than is given by a true country physician, as I was impressed while with them.

As regards prophylaxis in mining towns, the room, as far as furniture is concerned, is very often thoroughly fitted for a lying-in chamber, in that it is cleared of all upholstery except what is needed. . The nurse is generally the next door neighbor, although in an emergency good nurses can often be procured. Both nurse and doctor are usually called during the third stage of labor. Attention to antiseptic cleansing of hands and instruments of the physician appeals to the common sense of every reasonable practitioner. I see it recommended that "ergot should be administered after birth, and kept up in moderate doses three times a day for at least a week."

The use of ergot during the prevalence of this disease, unless absolutely necessary, I have abandoned. Early in my experience I was impressed with the fact that such tonic contraction of the uterus was caused by this drug as to tend to retention of the discharge, and thus add fuel to the flame; and my convictions were strengthened by the fact being impressed upon me by Dr. W., without previous acknowledgment to him of my suspicions. It may be prejudice, but I am convinced that those cases I refrained from giving ergot to were less formidable in their symptoms. The women were usually robust, and may not, therefore, need the treatment which is called for in city practice.

Laying aside all arguments as to what puerperal fever is, let me only state what I know of the treatment. I am convinced that marked benefit follows antiseptic vaginal injection, and two of my cases (the only ones lost during the epidemic) impressed me with the necessity of absorbing such advice as Dr. Thomas gives in the following words: "The physician must now decide whether, in his opinion, the septic disease which is developing has originated in the wounds situated between the os internum uteri and the vulva, or in the endometrium above the former point. If he decide in favor of the former view, he should persist for a time longer in the more thorough use of vaginal injections; if of the latter, intra-uterine injections should be at once resorted to. Usually the *question has to be decided by the efficacy or inefficacy of frequent germicidal vaginal injections in bringing down the temperature and controlling other grave symptoms.*"

Vaginal injections can be made by simply slipping a bed pan under the patient, and using a Davidson syringe, thus preventing all unnecessary movements on the part of the patient in order to move her to the edge of the bed. Frequently, and in all my cases, either metritis, cellulitis, or peritonitis, and sometimes pleurisy, developed early, and at once flaxseed poultices were resorted to, and were continued until pain and tenderness had disappeared, or the weight of the poultice, together with the heat, were objectionable to a now prostrated patient, when turpentine stupes took their place.

I would like here to say a few words about venesection, as your journal has had several enthusiastic articles appear in it lately favoring this mode of treatment in sthenic inflammations. Neither in this disease (though of a sthenic type), nor in pneumonia, or others of like character, have I ever had reason to regret the withholding of the lancet. Nor have I seen it used by any of my associates. Prompt use of heat, in the shape of flaxseed poultices, *properly made and applied*, together with aconite, bromide of potassium, and opium, have had such effect as to warrant my trust in them.

But besides antiseptic local treatment, in puerperal fever, we have the general system to look after. We have a patient laboring (often) under intense pain, incompressible, rapid pulse, very high temperature—which, of itself, is capable of doing immense damage, if allowed undisputed

sway. Where a high temperature, with an incompressible pulse, exists, a combination of aconite and bromide of potassium will be found efficacious:

℞. Ext. aconit. fl., gtt. xxiv to lxxii.
Potass. brom., ℥ ss.
Aquæ, ℥ iv.
Spts. lavand. comp., ℥ j.
M. Sig.—Tablespoonful every two hours.

It will be seen by the above that as much as six drops of the fluid extract of aconite is given every two hours, which same I have continued thirty-six hours with beneficial results, and have yet to see any deleterious effects from such heroic doses.

Bromide of potassium may be used as a febrifuge; if so, I do not see it advocated by the works on therapeutics, but long and continued use of it has convinced me of its efficiency; so much so, that in young children I seldom use anything else. It may be that its action is due to direct effect on the circulation, or by its quieting power over the nervous system, or these actions may be combined.

To relieve pain, opium (if there is no tendency to diarrhœa), combined with pilulæ hydrarg., is given every hour till pain is relieved. Should diarrhœa exist or set in, then a combination of opium, bismuth, and cinnamon, does good service. For the first stage, then, aconite and bromide of potassium every two hours—in doses indicated; poultices (flaxseed) every two hours; milk and (if nausea), lime-water, every two hours. I have seen stomachs completely upset by allowing them, where large amounts of nourishment were taken at one time, to drink milk whenever they desired to quench their thirst. Regularity in giving nourishment in disease is as necessary as in health. Of course, I say here every two hours, for in the first stage I have usually found digestion good.

And last, but not least, antiseptic injections morning and evening (time of visits).

I have often had the gratification of seeing a temperature fall from 104½° or 105° to 103° or 102°, and kept there. Pain relieved, pulse made compressible, tongue and skin become moist, thirst quenched, and rest, where, a few hours before, there had been agony. But in the course of the disease the time comes when aconite is contra-indicated and digitalis should take its place. It is also at this time that quinine seems to exert its greatest power. Having been taught to withhold quinine during the first stage of any sthenic inflammation and use it only after relaxation had been produced, I have seen such good effects of such treatment that I now pursue it regularly. The exciting qualities of quinine apparently add to the already agitated condition (of the first stage), and its tonic properties prevent that relaxation of system which we strive, by cardiac and other depressants, to produce. But let the pulse once become compressible, the skin moist, the brain quiet, and the whole system calmed, and then we see the opportunity to give our invaluable drug.

It may be, and usually is, the case that other stimulants are called for and brandy with milk, or if nausea exists, with milk and lime water, will often succeed in tiding a patient over what would otherwise have been collapse and death. No new drugs are here mentioned nor specifics lauded; but with proper handling of our well known medicines, we often are gratified by seeing marked results. In the epidemic of which I have written, in my own field two patients died. The one was on the road to recovery, but sat up in a chair the first day her temperature was normal, and also extended her diet. The evening of the same day her temperature rose up to 106°. Inside of forty-eight hours it was reduced to 102°. She died in about ten days, a pyæmic abscess forming in the right iliac region.

I have before remarked that my cases presented signs of cellulitis or peritonitis among the initiatory symptoms and that they were sthenic in their character. It may be that this will strike some physicians as rather peculiar. One author, writing on this subject, says: "But puerperal fever with peritoneal lesions may attack the patient after the most favorable delivery and without any obvious cause. Then the symptoms of the disease show that it has a special character, for in the puerperal fever, with peritoneal lesion, *the symptoms* of the *first stage of peritonitis are generally absent;* the *peritoneal symptoms* are those of *the second stage*, or of collapse, as for example, there is very frequently diarrhœa instead of obstinate constipation."

But another writer remarks: "The more, indeed, do we study the history of puerperal fever, the more prominently does the fact stand out that the type of the disease has varied much during the last hundred years; and that while, in one epidemic, the sthenic or inflammatory nature of the symptoms has been such as to warrant the boldest antiphlogistic treatment, in another, the asthenic type has prevailed from the first, when stimulating treatment has alone been attended with success."

"It is quite clear, however, that during the

last forty years the type of puerperal fever has been usually, although not invariably, asthenic or adynamic."

I know that the description of my cases will lead one to see that they were of the sthenic type. Whether this be due to the character of the epidemic, the unusually bracing and invigorating atmosphere of the mountains, or to the fact that the patients were of robust constitutions, or to all these combined, is a question. But though our cases differ from those generally seen, especially in the cities, may I hope that your pages are not taken up by useless material in thus occupying them by trying to give a glimpse of our treatment in the mountains, of this serious and prevalent disease.

PUERPERAL ECLAMPSIA.

BY WALTER H. PARCELS, M. D.,
Of Lewistown, Pa.

I was called about two o'clock on Sunday morning, April 6, 1884, to attend in confinement Mrs. S., aged a trifle less than seventeen years. I found the presentation normal, os uteri dilatable, head not yet engaged in the superior strait. The uterine contractions, which were mild at first, increased gradually in force and frequency, the os uteri dilated, the head descended; I mentally estimated the completion of labor by daylight. The woman was in hopeful spirits, complaining once or twice of a slight headache only; but as the pulse was normal or nearly so, and the face not flushed, to me the case seemed to be going along as regularly and as merrily as the chimes of a marriage bell. About five o'clock, however, she was seized with a *convulsion*, which was epileptiform in character, and came as unheralded as a lightning stroke from a clear sky. The convulsion lasted probably three minutes, leaving her in a semi-comatose condition. The child's head was now pressing upon the perineum, and needed only a few more pains for its delivery. Another convulsion followed a few moments later, and the woman became entirely unconscious, and all uterine contractions ceased.

The pulse became full and frequent. I immediately took about a quart of blood from the arm. Instrumental delivery at once, was my opinion, as to the next step to be taken; but as a consultation seemed desirable, I waited a little for the arrival of my friend, Dr. Sheaffer, who came within an hour, controlling the convulsions in the meantime with chloroform. The spasms recurred about every twenty minutes, the woman at no time regaining consciousness. On the arrival of Dr. S., I immediately delivered with forceps, the child being born alive, though it died thirty-eight hours afterwards.

We continued the chloroform treatment for possibly an hour, but the convulsions persistently returned. We then used hypodermically about a half grain of morphia, nearly the same dose being repeated about three-quarters of an hour later. The convulsions now became less violent and much less frequent, one interval being at least an hour and a half, when there was a slight *promise* of returning consciousness. As the effects of the morphia began to subside, the convulsions returned as badly as ever. About twelve hours after the morphia had been first used, nearly a grain was again hypodermically injected, the convulsions ceasing within an hour, not to return.

Whenever the patient could swallow, she was given bromide of potassium in large doses. After the cessation of the convulsions she remained in a semi-comatose condition for about thirty hours, when, awakening apparently from a sleep, she recognized her friends.

I should have added that she was kept under the influence of morphia for about twenty-four hours after the spasms had ceased to recur. The first urine that we could get was tested, and found to be, in bulk, nearly one-fourth albumen.

From this time on the case progressed well. Repeated examinations of the urine showed a gradual decrease of the albumen, which disappeared entirely in about ten days. During this time, tablespoonful doses, three times a day, of Basham's mixture were substituted for the bromide.

My object in detailing this case is to call attention to the apparent superiority of the morphia treatment over the usual modes. What is the condition of affairs which gives rise to the convulsions in puerperal eclampsia? The accoucheur takes command of the obstetrical case, the way is clear, he thinks himself marching bravely on to victory, and toward new fields of conquest, when suddenly he encounters a "lion in the way." He must act at once, time is precious. Are these convulsions hysterical? Do they depend upon a sudden determination of blood to the head, congestive apoplexy? May there be a condition of uremia, and these convulsions be the result of a toxic agent acting upon the brain? In my opinion, nearly all the very serious cases are of this last variety. How, then, shall we proceed? Venesection is certainly the first indication. In a discussion of this subject, which I heard some years ago, a physician took the ground, that as the

blood in its poisoned state is the cause, we should get rid of as much of it as possible. "Yes," said another, whose sense of humor was always uppermost, "let us take it all out, *boil* it, and pump it back again."

The proposition to bleed freely is certainly based upon a sound theory. If it be true that the poisoned blood, coming in contact with the nerve centres, is the sole cause of the convulsions, is it not true that the injurious effect will be in proportion to the amount of said blood? Though "the blood is the life," we must lessen it, for it contains in this instance, carefully concealed, the seeds of death. Venesection performed, what next? What is the pathological condition of the kidneys? Is the case one of chronic Bright's disease? It may be, and if so, death will probably claim his own sooner or later, no matter what our treatment may be. Are the kidneys inflamed? Possibly so; but probably they are only congested as the result of pressure of the gravid uterus. The indication, then, is to remove this pressure as speedily as possible, and nature, even unaided by art, will do much toward restoring the normal condition of the kidneys. If we can, we must deliver at once. What next? Control the convulsions with some agent which will partially paralyze the nerve-centres, and wait for the urea to be eliminated from the blood. For years chloroform has been, at this stage of the case, the standard remedy for controlling the convulsions. Why rely upon chloroform? Anæsthesia, unless the inhalations are repeated, will be temporary only, and the convulsions will return. The effects of morphia will continue for a period of from eight to twelve hours. Is there a better treatment than this? Uræmia as a cause of puerperal eclampsia was first recognized only about thirty years ago. The onward march of science is irresistible. The future may produce a remedy which will act like a talisman. Will transfusion be the strong arm which will be reached forth to save these unfortunate women? Will the poisoned blood be drawn off and blood from the arm of a healthy person be substituted? Or, better yet, will a drug be discovered which, being used hypodermically, will render urea inert and harmless?

TREATMENT OF INEBRIETY.

BY T. D. CROTHERS, M. D.,

Superintendent Walnut Lodge, Hartford, Conn.

Having separated the patient from all bad and unsanitary surroundings, and taken alcohol from him, the question of medical treatment that will build up and strengthen the organism comes up prominently.

This will vary largely with the condition and history of the case. It should be remembered that nearly every organ of the body will exhibit signs of derangement, functional and organic symptoms of every grade and description will appear and disappear like shadows. The treatment should begin with inquiry as to syphilis. If any suspicion of this affection can be traced, bichloride of mercury or the iodide of potassium must be combined with tonics for a sufficient length of time to get full constitutional effects. This is to be followed by small increasing doses of Fowler's solution, taken with great regularity for months.

For the insomnia and spinal reflexes so common during the first few weeks, a preparation which is very finely prepared by Park Davis & Co., Detroit, has been found of great value. It is as follows: in each fluid ounce are, ℈3 chloral hydrate, ℈3 potassium bromide, 50 minims fl. ext. gelsemium, 40 minims tinct. opium. Of this take a teaspoonful every hour until relieved, or a tablespoonful at bedtime. Where danger exists of the patient continuing the use of opium, hyoscyamus in the same proportion may be substituted for the opium. This mixture can be given for the first two weeks, and should be alternated with single doses of chloral, bromide of sodium, and extract of lupulin, given in much larger doses than laid down in the books. The Faradic current will be found of great value in some cases as a hypnotic, and should always be used or tried to test its value. In some cases it is injurious, and cannot be given. Tinct. gentian and acid phosphate are found to be excellent tonics given in water before eating.

Where well marked congestion of the liver and kidneys exist, saline mixtures or waters are found very useful, taken in the morning before eating. A good mixture of this kind is bitartrate of potassium, and potassii et sodii tartrata, in equal parts, one-half an ounce at a dose, every day or alternate days.

Where evidence of great nerve and brain disturbance exists, strychnia in some form is found to be of great advantage. Given in doses from one-eight to one-sixth of a grain, twice or three times a day for two weeks, then alternate with tincture of iron, twenty drop doses, three times a day for the same length of time.

Of hypnotics, after the first few weeks, the mildest of this class should always be used, for in many instances they will be found more effectual than the stronger ones. Hydrate of chloral is

not a safe or reliable narcotic in many cases. The functional and organic heart troubles so common in this class, make it a dangerous remedy. Bromide of sodium is not without danger, and should be given in large doses for short periods, and then withdrawn, and be followed by some preparation of strychnia. Horsford's acid phosphate has a great value in many cases, and should be used always where it can be obtained. It will be found advantageous to vary the tonics and narcotics frequently, after the first few weeks, and often give nothing but mental remedies, such as sweetened water and other harmless compounds for several days. After this the effect of tonics seem to be more marked. Preparations of cinchona and gentian, or any of the simple bitters, cannot be used long without causing an inordinate appetite and consequent derangement of the digestive organs.

Hence, iron, arsenic, and strychnia, are to be preferred. Tinctures of any form are to be avoided, as in most cases an almost inappreciable amount of alcohol will be felt by the patient, and rouse up an insane impulse that can with difficulty be controlled. Frequent baths and nutrients, regulated diet, and resting in bed, are also of great importance.

The medical treatment of inebriety should always be based on the fact that the patient is profoundly degenerated, both physiologically and psychologically. No matter what the appearance, or his pretentions to health may be, no specific remedy will ever be found.

For the drink paroxysm of the dipsomaniac, morphia, concealed in large doses of extract of lupulin, is often of great value. Where morphia can not be used with safety, cannabis indica can be substituted. But the Faradic current, hot baths, and strong nutrients, should always be used. The value of medicines in these cases should be studied with care and watchfulness. Collapse from heart failure, hemorrhage in the brain, sudden inflammatory action, paralysis, etc., are likely to come on any moment, and the line of treatment must change accordingly. Each case should be studied by itself, and receive the best therapeutic skill possible. All routine treatment will fail, and the study of the physician should be to find the best general tonics, and the mildest sedatives that can be used in conjunction with various other means to restore and build up the weakened, diseased, and perverted organism.

—Dr. Wood, the inventor of the hypodermic syringe, died recently at his home in Edinburgh.

ON THE TREATMENT OF MEMBRANOUS CROUP.*

BY R. W. HUTCHISON, M. D., M. R. C. S.,
Of Queens County, N. Y.

The most interesting part of the subject to us, as practicing physicians, is to ascertain what is the most successful plan of treatment to adopt in pseudo-membranous croup—the plan that will enable us to save the most lives.

If we look at statistics, we discover that the mortality is literally frightful; it is generally set down in works on medicine as 19 in 20! And looking over the cases that I have seen during the last twenty-five years, both in my own practice and that of others, I think I may truly say that up to a very recent date, that statement is not exaggerated.

Of course, there are many reasons to account for so great a fatality: 1. And the chief one, probably, is the fact that the friends do not fully appreciate the danger, so that the patient is very often moribund before medical aid is obtained. 2. Another reason for the high mortality in pseudo-membranous croup is that the remedies generally used are too depressing—too much reliance being placed on emetics. Viewing the ailment in a different light from that in which it is generally viewed, looking at it, in fact, as a kin of diphtheria, if not the actual disease itself, and using a more tonic and supporting plan of treatment, we ascertain that life is more often prolonged, and the physician thus enabled to combat more successfully against the local phenomenon, which is generally the immediate cause of death. 3. Another cause of the great mortality of pseudo-membranous croup is that at the present we know of no remedy that will prevent the formation of the membrane, or rapidly dissolve it when formed. True, various medicines have been used, both locally and internally, with that object in view, such, for instance, as mercury, iodine, bromine, lactic acid, calcium, etc.; some of which may be set down as harmful, while others as operating too slowly.

I have tried almost everything I have seen recommended, except lactic acid, and in my hands most of them have proved failures. I have very little confidence, therefore, in the internal remedies that I have tried, except, perhaps, copaiba, guaiacum, and benzoate of soda, with which, in addition to the inhalation of lime-water, I have saved about half the cases that I attended during

*Abstract of a paper read before the Queens County (N. Y.) Medical Society.

the last few years. I think, for the present, we must rely more on local remedies, applied by means of one of the various apparatus in use to atomize liquids. This must be resorted to almost uninterruptedly day and night until the symptoms show a disposition to yield, and then less frequently. The room in which the patient lives should, moreover, be kept saturated with steam. I have generally advised an open vessel to be kept boiling with lime-water. I think this gives more relief than the simple steam; so that it is possible that the lime has a dissolving action on the membrane. 4. Another reason why diphtheritic croup is so fatal is that when it comes to the last, when it becomes apparent to all that the little sufferer is actually strangling to death, and must soon cease to live unless some relief be afforded, the medical attendant stands by, or more often leaves the sick room, and thus allows grim death to gain the victory without making one more effort, even though it called for the use of the knife. But very often the physician proposes tracheotomy, and strongly urges it; but the friends are obdurate. "No," they say, "I would rather that the child should die than to have its throat cut." So that between the two, the timidity of the medical attendant and the impossibility of obtaining the consent of the friends, we hardly ever hear of tracheotomy in the country. Indeed, I very much doubt whether one physician in three has ever seen the operation performed. And if an inexperienced surgeon should consult almost any work on surgery with the view of obtaining a more accurate knowledge of the subject, he is almost sure to relinquish the idea of making his first attempt, from the numerous frightful stories that are there depicted in detail.

Hospital Reports.

CLINIC OF OPHTHALMIC DISEASES, HOTEL DIEU, PARIS.

LECTURE BY PROFESSOR PANNUS,

On Revulsion in Inflammatory Affections of the Eye.

Gentlemen: Two patients are before you for consideration to-day; one has been suffering from keratitis, the other from irido-choroiditis of an obstinate kind. In both these cases the revulsive method of treatment has been of singular efficacy, all internal remedies having failed.

The first patient, whom you saw at the last clinic, and who now presents himself before you, that you may be witnesses of the very marked improvement which has taken place in his pathological condition, has long been laid up by a very painful inflammation of the cornea, with intense photophobia; the application of the actual cautery to his temples has caused the pain entirely to disappear, and has apparently arrested the inflammatory process.

The second patient has been treated by the potential cautery (*i. e.*, by an issue) to the temporal region. This patient, affected several years ago by irido-choroiditis of the left eye, was treated for a long time by one of my colleagues, but without benefit. An iridectomy became necessary on account of the numerous adhesions which formed. Despite this operation, amblyopia persisted, and a morbid condition of the vitreous remained.

A short time since this patient consulted me about her right eye, which was suffering from the same series of symptoms which had characterized the onset of the disease in the left eye. The surgeon who had treated her before was urging her to submit at once to iridectomy, in order to arrest the lesions of irido-choroiditis at their commencement. It did not seem to me advisable then to resort to so radical an operation, and, as some of you are aware, various other measures were adopted; iodide of potassium and mercurials were given, then we tried sudorifics, quinine, and salicylate of sodium. Vapor douches, compresses (hot and cold), instillations of atropine, then of eserine, were all employed without success; we even punctured the anterior chamber, we kept the patient in total darkness, and yet all without result. At the end of two months of fruitless endeavors to benefit the poor patient, the photophobia, the lachrymation remained the same, the redness of the eyeball had not diminished, though happily the movements of the pupil were conserved, and there was perfect dilatability. Not being willing to practice iridectomy for a healthy iris where there were no adhesions, I determined to try the effect of an issue over the temporal region in the vicinity of the affected eye.

During the first three or four days after the establishment of the issue, but little change was noted; only the pains had somewhat abated; from the fourth day, however, after the separation of the eschar and the commencement of suppuration, there was a remarkable arrest of the inflammatory symptoms, and the photophobia disappeared. All internal treatment was stopped; the atropine drops were continued. The sore was kept open by binding in a pea, which was kept in place for six weeks, and to-day the patient is perfectly well. You remark at the upper part of the cornea a crescentic zone of sclerosis, which is all that remains to show that the disease existed.

This means of revulsion, which succeeded so well in this case, has rendered me the greatest service in my hospital practice. We have an instance in point in A. B., Ward H, a victim of intemperance, who came here with keratitis attended with hypopion and ulcers of the cornea. The cautery arrested the march of the disease, and to-day he is fairly convalescent.

I exhort you, then, to have faith in revulsion, but the revulsion must be done thoroughly. Whether you use the actual or potential cautery, it must be made to penetrate deeply the subcutaneous cellular tissue and provoke suppuration. This is a practice of ancient date, which has been too much abandoned these modern times. The

application of the cautery may be made to the temple, where it may be concealed by the hair, or to the mastoid region.

I cannot advise the use of irritant caustic injections, as of nitrate of silver, or corrosive sublimate, advised by some surgeons, for it is hard to manage the effect of these injections, and troublesome erysipelatous inflammation may result. Nor is the seton by any means as efficacious as the cautery.

If you resort to the cautery, you may use punctiform cauterizations made by galvanism; the hot iron (which is the old-fashioned method), or the potential cautery, produced by some strong caustic, as Vienna paste. You first apply the caustic and produce an eschar; then when the slough is separated, you fasten between the lips of the sore a pea or some other foreign body, and keep up a long suppuration.

Punctiform cauterization and vessicatories fail completely in the inflammatory period of the malady, while remedial in later periods, when the pain is severe, and when tendencies to abatement of the malady are seen. Then it is the most powerful means of precipitating a cure, and of combating certain obstinate neuralgias which persist after the inflammatory redness has disappeared. The suppurating cautery is an excellent means of combating the development of ophthalmias in the inflammatory period, and it was by accident that its efficacious action was demonstrated to me. While directing the service of syphilitic eye affections at the Hospital Midi, I had a patient affected with syphilitic iritis, of a sub-acute kind, with atrocious neuralgic pains. The regular treatment was instituted, but nothing seemed to help the severe pains, and I had to resort to repeated morphine injections, which alone gave relief. I used to prick the morphine into the temple every morning, when one day, by mistake, the syringe was charged with a ten per cent. solution of nitrate of silver. The patient uttered a terrible shriek, and almost immediately the symptoms of sphacelus and inflammation commenced. A severe phlegmonous swelling resulted. Poultices were found necessary, and there was soon quite a profuse suppuration. The cellular tissue mortified, and was eliminated, and there was an exfoliation of the aponeurosis covering the temporal bone, flakes of this aponeurosis coming away in the discharge. The fact to note is, that with the establishment of these inflammatory accidents provoked by the injection, we saw rapidly disappear all the eye symptoms which previously tormented the patient. The pain, the photophobia, the lachrymation, ceased, the ocular injection went away, and the recovery was prompt and thorough, without any synechia.

In a similar case which came under my observation in the Hotel Dieu, a violent rheumatic iritis disappeared rapidly on the development of facial erysipelas which invaded the sub-cutaneous cellular tissue.

Despite the good results which attended my accidental injection of nitrate of silver, I cannot advise you to resort to this means in your practice, for the issue will give you equally good results, without the same risk.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

A regular meeting of this society was held on the 16th inst. (June), when a number of important papers were presented. The first was by Dr. Wm. E. Quine,

On the Significance of Jaundice in Diagnosis,

The following brief synopsis and summary of which is here appended:

After alluding to jaundice of obstructive and non-obstructive origin, and to the various theories that have been advanced in explanation of the latter, the writer succinctly pointed out that the attendant symptoms were mostly due to the presence of colorless bile acids, the bile pigment being harmless. Cerebral disturbance, due to hepatic derangement, and associated with cholæmia, was not caused by the presence of normal bile, but by a different though unexplained species of toxæmia. Although slight, jaundice is often overlooked, and in some instances cannot be distinguished from cachexiæ, except by the discovery of bile acids in the urine. The diagnosis usually relates to the discovery of the cause, and not to the mere recognition of the effect. Seventeen main points of the paper are mentioned:

1. Jaundice occurring suddenly, in apparent health and painlessly, is usually of emotional origin and transitory.

2. When it depends on disease or injury of the brain, acute atrophy of the liver, snake poison, or an infectious fever., it is always associated with mental disturbance.

3. If it be attended with fever, and well marked, it is secondary to inflammation of biliary passages, pneumonia, toxæmia, or infective inflammation of the portal vein.

4. If it occur suddenly, and is preceded by paroxysmal pain and vomiting, it is caused, nine times out of ten, by biliary calculi.

5. If it is preceded by typical symptoms of gastro-duodenitis, it is obviously of catarrhal origin.

6. Impassably, obstruction of the common duct is shown by great intensity of jaundice, clay-colored stools, and, in recent cases, by distension of the gall bladder.

7. Jaundice caused by sudden obstruction of the biliary passages is always associated with paroxysmal pain and nausea, but there is no means of ascertaining the nature of the obstructing body, except its discovery in the stools.

8. In rare cases of sudden obstruction by cancerous, hydatid, and aneurismal tumors, there is almost always a history of impaired health, enlargement and deformity of the liver, ascites, etc., which, aided by the revelations of physical explorations, will lead to correct differentiation.

9. Sudden return of normal coloring to fæces confirms the diagnosis of obstruction.

10. Occlusion of the cystic duct may be attended with as much pain, nausea, and distension of the gall bladder, as occlusion of the common duct, but there is no jaundice. In occlusion of the hepatic duct, the same symptoms are present, including jaundice and excluding distension of the gall bladder. It is impossible to distinguish between occlusion of the hepatic and the common duct.

The former is rare, because the duct increases in size from above downwards.

11. If jaundice persist after the symptoms of biliary colic or catarrhal inflammation have a month since disappeared, or if jaundice have disappeared after a biliary colic, to return slowly and painlessly, it may be assumed that stricture of the duct has resulted from inflammatory thickening, adhesion of walls, or cicatrization of an ulcer.

12. A history of repeated attacks points to the probability of gall-stones.

13. If jaundice come on slowly, without antecedent colic or catarrh, and without attendant evidence of impaired health or portal obstruction, it is probably caused either by pressure upon the duct, or by the growth of a tumor within its walls. The pressing body, when large enough, may be readily appreciated, as in the case of pregnancy, ovarian tumor, aneurism, distended colon, etc.; but when it is small, or constituted by enlargement of lymphatics in the fissure of the liver, it is apt to escape detection.

14. Slight but persistent jaundice may be due to incomplete occlusion of the common duct, or to complete occlusion of a branch of the hepatic, but usually it is found associated with either valvular disease of the heart, some disease of the lungs which obstructs circulation, or cirrhosis of the liver.

15. If ascites be associated with it, the disease is either cirrhosis or cancer of the liver. If the liver be abnormally small, the disease is cirrhosis; if it be large, the disease is either hypertrophic cirrhosis or cancer. Differentiation between the two is seldom attended with difficulty.

16. Absence of jaundice does not imply absence of hepatic disease, since the liver may be destroyed by disease, or extirpated by operation, without jaundice ensuing.

17. It is not a prominent symptom of hepatitis, if catarrhal inflammation of biliary passages be rigidly excluded. It is not characteristic of hepatic abscess, when, at most, mere muddiness of the complexion is usually seen. These affections are rare in temperate latitudes, and when encountered are generally found to be secondary to direct injury of the liver, or to infective inflammation of the portal veins. It is not a symptom of waxy or fatty liver, or of hydatids, excepting as an extraordinary complication.

Discussion was participated in by .

Dr. G. C. Paoli: Sometimes in grave maladies such as schirrus of the liver, very little icterus oftentimes is present, so that a mere tint only of pigment may be noticed in the skin. Many times, no doubt, there may be serious disturbance going on in the liver, and we will notice a yellow condition of the conjunctiva; yet we pass it by as something of slight consequence.

Dr. S. H. Stevenson inquired if cholesterine and the obstruction of the gall duct would produce toxic effects upon the brain, or other cerebral disturbance?

Dr. A. R. Jackson expressed his admiration of the paper—it was a paper, he thought, to commend to others, and that we should emulate it. It was full of many interesting points, and devoid of superfluous verbiage (padding, as he styled it).

Dr. J. H. Etheridge inquired if during mental emotion a patient might not greatly become jaundiced? Also, is it not a fact that in pigmentary substances there may not be more than one kind of coloring matter? Also, in those hurt or injured after reaction, if jaundice comes on, is it due to the shock to the nervous system or through the vascular system?

Dr. J. J. M. Angear stated: "Physiology says bile destroys the red corpuscles of the blood; others state that the coloring matter of bile is nothing more than the coloring matter of the blood. Why not, then, take the hypothesis, that when the conjunctiva and mucous membranes become discolored, that it is due to a poison entering the blood? In clay stools, 'tis said, if they come from the large intestine, that the odor comes from here also, and yet to give mercury produces dark, offensive stools, because it acts upon the liver."

Dr. Quine closed by stating it has not been proven that bile is toxic, or that it produces cerebral disturbance. The blood and secretions may be saturated with bile for years, and there is no cerebral disturbance as a result from it. In obstruction of the common duct there is no phenomena developed of cerebral disturbance. Some of the questions propounded he could not answer, nor did he know where to direct the members to look for the necessary information.

This was followed by Dr. G. F. Hawley, who read an interesting thesis on

The Effect of Noises upon Certain Forms of Deafness.

More than two hundred years ago Dr. Thomas Willis, of Amsterdam, described a certain form of deafness in which hearing was improved by noise, enabling persons to distinguish tones and sentences which at other times would be unheard. This symptom, bearing the name of Paracussis Willisiana, has been accepted by most aurists, but no satisfactory explanation as to its cause has been advanced. While Politzer, von Trollsch, and others, consider that it depends upon some change in the position of the ossicles or membrana tympani, many, like Krama, take different views, and believe that it is due to a stimulating of the auditory nerve, thus forcing it to a more healthy action. Experience favors the theory that the middle ear is the seat of this symptom, that some change is brought about by the constant noise which restores the hearing for the time being. What this change is is still open to discussion. It may be of interest to relate the following case which came under my observation while house-surgeon at the Golden Square Hospital, London: Mrs. H., aged thirty, had, for the last five years, suffered with marked deafness in both ears. Common conversation was heard with difficulty, except when any loud noise was present. At that time the hearing, apparently, was greatly improved. A watch could be heard on the left side only upon contact, and on the right at a distance of about two inches. The tuning-fork showed no trouble of the acoustic nerve, but clearly indicated some disturbance of the middle ear. The drum-head was normal as to tension, color, etc., while perfect movability existed in the mallio incuidal joint. Nothing indicated anchylosis of any of the ossicles. The appearance of the throat

was healthy, and the Eustachian tubes both patent. This is a good example of this form of deafness in which the symptoms of hearing in a noise manifests itself. Roosa, however, mentions two cases where the drum-head was more or less destroyed, and still noises improved the hearing. The ossicles in both cases were intact. Politzer, in his work on aural surgery, states that this improvement is seen only in middle ear affections of an adhesive or schlerotic character, and regards it as a most unfavorable symptom for satisfactory prognosis. Roosa, on the contrary, states that it is found in many forms of ear affections, and does not necessarily forbid one from expecting favorable results from treatment. In his article on "The Effects of Noises Upon Diseased and Healthy Ears," he says: "I have known two cases where this symptom occurred in patients who regained their hearing perfectly. While the symptom frequently accompanies incurable diseases of the middle ear, I believe it is a very frequent symptom in subacute cases, where both ears are affected. Of course, it would not be observed in disease of one ear only. Whatever may be the cause of this symptom, we are justified, the writer thinks, in believing that certain pathological changes are then present in the middle ear, which will be found at no other time. If this be true, in what does the change exist? Willis considered the change brought about by the action of strong wave tone upon a relaxed membrana tympani to be the cause of this symptom. As long as the drum-head is in a relaxed condition, it refuses to respond fully to wave impressions. It is no longer a perfect sound conductor until its tension is restored. Noises, by forcing air against the membrane, press it inward, restore its tension, and hearing is improved until the pressure is removed, when deafness returns as bad as ever. If this improvement was found only in such cases as he describes, we might accept his theory as correct; but unfortunately, as already stated by the writer of this paper, it is present with no change whatsoever in the drum-head. Therefore, in such cases at least, this improvement in hearing is due to some other cause. We have in the middle ear two other elastic membranes, one of which taking as important a part in conveying wave impressions as the membrana tympani, any change by disease or injury would be fully as disastrous to normal hearing, *i. e.*, the writer means the membrane of the foramen ovale. When we consider the extraordinary fine shades of vibrations transmitted by this membrane to the fluids of the labyrinth, are we not justified in expecting that any loss of accuracy and precision on the part of the transmitting apparatus at this point will cause a corresponding loss of hearing power? According to Riesmann, the excursions of the stapes in the fainter tones are so small as to escape detection, even with the highest power of the microscope. Therefore a corresponding sensitiveness on the part of the membrane must necessarily be present, in order to appreciate and transmit these vibrations. Thus we see that any change in the membrana ovale which tends to hinder the passage of the vibrations to the fluids in the inner ear must cause diminution in hearing. If, then, the membrane from any cause becomes relaxed and loses the power of responding to vibrations, it acts no longer as a sound conductor, but as a damper to any wave impressions. This is demonstrated in the case of relaxed drumheads where inflation improves the hearing. Not only must this elastic plate (so called by Politzer) be capable of responding fully to any wave impulse, but it must also bear a certain relation to the foot of the stapes, *i. e.*, a due amount of pressure must be applied by the stirrup, and a sufficient resistance be offered in every ear that possesses perfect hearing. If this is lost, deafness is the result. Chronic suppurative inflammation of the middle ear, with destruction of drum-head, incus, and mallius, is a proof of the correctness of this statement. Hearing is here frequently improved by a false drumhead, which presses the loose stapes against the membrane of the foramen ovale, thereby restoring the relative positions of the parts. In a relaxed membrane, the pressure of the stapes is wanting, due to an absence of resistance in the diseased membrane ilself. Until we find some means of restoring this needed resistance, deafness remains. Thus, through the loss of elasticity in this membrane we lose two important factors for perfect hearing. First, this membrane, like the membrana tympani, while relaxed, refuses to act as a conductor of sound by not responding to vibrations given it; and second, the proper relation between it and the stapes is destroyed, the necessary pressure and resistance being absent. We find in the case of an atrophied drum-head that hearing is frequently improved by inflating the middle ear, which restores the tension to this membrane by forcing it outwards. One might suppose that such inflation would likewise restore lost hearing, if due to a relaxed membrane at the oval window. Unfortunately, the same act which might restore to this membrane its proper tension, forces it inwards as well, and thus separates the stapes from it.

Though the membrane may be in a proper condition for receiving and transmitting wave sounds, the stapes, from the absence of any pressure applied by it to this membrane, will be unable to perform its duty. There will be more or less obstruction to the passage of sound at this point. Whatever these restore, the hearing in these cases must not only renew the tension of the membrane, but maintain as well the relative position of health between it and the stapes. This, in the writer's opinion, can only be accomplished by some influence brought to bear upon the membrane and stapes from outside the middle ear. If now we consider the effect of wave impulses upon the membranes and ossicles, we can understand how a loud and continuous noise (as the writer thought) might improve the hearing, where the deafness is due to such pathological changes as herein described. The air, set in motion by this noise, strikes upon and pushes the drumhead and ossicles inwards. This crowds the air in the middle ear against the membrana ovale, which, if relaxed, is made tense by this pressure. At the same time, the relative position between it and the stapes, as to pressure, etc., is also restored, and hearing for the time is therefore improved. This noise, which would confuse one with normal hearing, is absorbed, so to speak, in removing the cause of deafness. In case of perforated drum-

head, the vibrating air acts directly upon the diseased membrane and stapes.

Von Trollsch mentions a case where a magistrate so afflicted improved his hearing by pressing a bit of stick against the drum-head. Allen also, in his work on aural surgery, states, while speaking of this symptom, that the hearing power was increased in a patient who presented herself with marked destruction of the drum-head, by pressing cotton against the ossicles. Another is also noted, where a large perforation existed. Here, before and after the healing of the perforation, hearing was improved by pressure. Though these three cases do not in themselves place this theory beyond dispute, it may still make it worthy of consideration. It may encourage us to further investigations, which perchance may result in establishing beyond a doubt the cause of improved hearing in certain forms of deafness by noise.

Discussed by Dr. S. J. Jones, who stated that this subject interested pathologists very much, that different causes will produce this condition, and it is therefore not always dependent upon the same cause. A noise that will affect an abnormal ear in this manner may have no effect on the normal ear. Cotton pressed over the stapes will increase the hearing power in these cases. A tuning-fork placed between the teeth is also better heard in the affected ear; and so, to place the hand on a piano, the affected ear is excited to action during the transmission of delicate sounds, and they are best heard in this ear, more so than in the normal ear.

After which Dr. Wm. L. Axford gave a verbal report of a case he operated on by performing median lithotomy for the relief of an unusual case of hyperæsthesia of the urethra and cystitis occurring in a man of 66 years of age, of inherited gouth dirthesis. He had suffered from repeated attacks of nephralgia during the past eighteen months. He also had enlarged prostate, and morphia, belladonna, suppositories, etc., had little or no effect. Catheterization was attended with great agony, the pain being so excruciating as to continue for hours after this procedure. But there were no strictures of the urethral canal, and as a last resort the operation was done. This relieved him very much, but the patient died in a few days. The cystitis was of long duration. The urine was very ammoniacal and fetid.

Dr. C. T. Parkes then cited briefly two cases where he performed this operation for cystitis; the relief was of six months' duration.

The last speaker also presented a fine specimen of double ovarian tumor, removed a few days since, after which the society adjourned.

L. H. M.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Continued from page* 41.)

Dr. Drysdale regretted that Dr. Beates had not sent him a specimen of the fluid removed from this tumor, especially as he had more than one opportunity of doing so. While having the highest regard for the opinion of the gentlemen who examined it, still, so many errors had been made in these investigations, that it would have been a satisfaction to him to have examined it himself. But apart from this regret, he considered it by no means proven that the cyst in question was not ovarian. The portion of tumor left attached to the uterine wall in the specimen resembled a closely adherent ovarian cyst, such as he had met with repeatedly. The little mass lying close to the uterus, described as an atrophied ovary, did not present any resemblance to an ovary, nor did it occupy the usual position of that body. In the description no reference had been made to the color of the tumor, which has an important diagnostic value; the uterine fibro-cyst being usually livid or purplish in color, while the ovarian had a white pearly hue. It was especially in cases like that of fibro-cyst of the uterus where the importance of the ovarian cell in diagnosis was well marked. In his investigation of these tumors, he had never met with the cell which he had described as ovarian. Mistakes were very easily made in the differential diagnosis of such tumors, and in fact in many cases the diagnosis could not be established except by the examination of the fluid, or by opening the abdomen. For want of this examination of the fluid, he had seen Spencer Wells make the abdominal section to remove a tumor which he had diagnosticated as ovarian, but which proved to be uterine. Dr. Marion Sims had sent him on three different occasions—and without telling him that they were from the same patient—specimens of fluid which he thought was ovarian, obtained from a cyst in the abdomen. Dr. Drysdale assured him that the fluid was not ovarian; but, after the examination of the last specimen, Dr. Sims, still doubting, determined to operate, and found a uterine fibro-cyst. The history and all the characteristics of the tumor described this evening were ovarian, and the specimen and autopsy were not sufficient to establish the diagnosis of uterine cyst.

Dr. B. F. Baer remarked that the specimen seemed to be a section of a fibroma arising from the uterus, but it is too small to be satisfactory or to prove its origin. His personal experience has taught him the diagnostic value of the Drysdale corpuscle. When Dr. Formad reports finding this cell in the fluid removed from an abdominal tumor, he feels strengthened in his diagnosis of an ovarian cyst. He has not trusted to the cell alone, but has been greatly influenced by its presence or absence in making up a diagnosis in doubtful cases. In every instance in which Dr. Formad has reported finding the ovarian cell, operation has proved the tumor to have been of ovarian origin. He would like to ask Dr. Drysdale if he still considers the cell pathognomonic.

Dr. Drysdale still believed in the pathognomonic value of the ovarian cell. In his investigations he had met with but one exception to the rule, and that was in renal cysts. To prove that the cell could be relied on to establish a diagnosis, he would give one or two instances where it was impossible to do this except by its aid. In a review by Dr. Harris of the Transactions of the American Gynecological Society in the *American Journal of Medical Sciences*, will be found this statement: "On one occasion Prof. D. Hayes Agnew gave Dr. Drysdale a fluid for examination, in which he found the characteristic cell. Upon stating what he had found to Dr. Agnew, he was told that the fluid had been taken from the abdominal cavity;

upon which he immediately said that the fluid must have escaped from an ovarian cyst, for it was ovarian. In this he was correct, as the cyst had a small hole in it, as if made with a punch, and the fluid had escaped as claimed." In another case Dr. D. received a letter from Professor Matthew D. Mann, of Buffalo, N. Y., with a specimen of fluid consisting of eight or ten drops, which the doctor stated was all that he could obtain by aspiration. The tumor had been diagnosticated by other surgeons as one of uterine fibroma, and consisted of a large solid mass, which filled the pelvis and abdomen as high as the umbilicus. The history and symptoms all pointed to a uterine fibroid, and the patient was in such a precarious condition that an exploratory operation was considered unjustifiable. An examination of the fluid by Dr. D. showed the presence of the ovarian cell. This determined Dr. Mann to operate. He found two ovarian tumors, which he removed successfully, and the patient recovered. "Without the microscope no certain diagnosis could have been made, except by resorting to an exploratory incision." These cases, and he could give many others like them, were sufficient to show the diagnostic value of the cell.

Dr. Beates remarked that it was a matter of extreme regret to him that Dr. Drysdale did not have an opportunity of examining the fluid; it was due to the fact that the neoplasm was regarded as ovarian, and the specimens of fluid were not preserved. At the autopsy the growth was presumed to have arisen from the left ovary, and none of the fluid was kept. Later study of the specimen disclosed that the amygdaloid mass was situated in an atrophied membranous structure, closely approximated to the uterus. The microscopic examination of this determined its ovarian character to the mind of Dr. Formad, which conclusion dissipated a doubt in my mind, and confirmed my belief of its being the left ovary. I thoroughly appreciate the strong probability of error liable to occur in positively diagnosticating by differentiation the Drysdale corpuscle from similar bodies, as the pyoid body of Lebert; but the fact that treatment with acetic acid only had the effect of rendering the whole corpuscle very slightly clearer, and disclosed no nucleus; that ether, added to the fluid, and the mixture thoroughly agitated for several minutes, had the effect of simply rendering the corpuscle paler, convinced me that the bodies were the corpuscles in question. There is, by very extended experience, developed a capacity to differentiate by a varying degree of opacity. Dr. Formad believed these corpuscles to be those of Drysdale. The striking phenomenon, if this be an ovarian cyst, is in the fact that primarily it was purely cystic, typically so, and that during the last year of its existence the cyst wall, throughout its posterior seven-eighths, assumed a myomatous development. If this did not occur, the myomatous wall must have originated at the fundus uteri, and gradually permeated the cyst. Either of these processes is almost incredible, and certainly exceptional to known clinical facts. The true uterine origin must not be forgotten. That a proper conception of the tumor may be formed, it should be compared to a large pumpkin, with a wall varying in thickness from one to three inches. For an area of about nine square inches at the umbilical region, the ordinary cyst-like structure formed as it were a drum-head. This wall is not fibromatous, but purely myomatous. Dr. Goodell had seen this patient and diagnosticated the tumor as ovarian.

Dr. B. F. Baer exhibited a specimen of hypertrophied uterine mucous membrane. R. H., æt. 30, maried twelve years; sterile; puberty occurred at age of twelve, slight dysmenorrhœa from the first, and since her marriage the difficulty has been increasing, so that during the last few years the pain has been very severe. The menstrual flow, which has always been rather profuse, especially since her marriage, has for more than a year been irregular in time and quantity; sometimes it continues two weeks very freely, when she would be so prostrated as to be compelled to remain in bed to regain strength. She complained of a severe, sharp pain in the region of the left orary radiating to the groin and anterior part of the thigh, and to the præcordial region and side of the head to the top-head. She had great dragging in the pelvis and pain in the sacral region. During her periods, the mammary glands would swell and become very tender and sore. Coition had become almost intolerable on account of pain during the act, and because it increased the pain in the left ovarian region, and induced a sensation of nausea and faintness. She had such dread of sexual congress that an interval of months would sometimes elapse between the acts. Her weight had decreased from 146 to 117 pounds, and her appetite and digestion were poor.

Examination showed the cervix uteri to be near the vaginal orifice, somewhat elongated, and conical. The os was papulous, the body of the uterus very much hypertrophied and retroverted. The left broad ligament was contracted, and the corresponding ovary prolapsed, larger than normal, and very tender to pressure. The sound indicated a uterine depth of three and one-half inches, and the cavity was large and soft. The organ was mobile. Ether was administered, the cervix dilated by means of Ellingen's dilator, and the endo-metrium was carefully curetted, removing a large amount of the most enormously hypertrophied mucous membrane. Nitric acid was applied. Under a regulated diet, with rest, complete relief followed, with freedom from hemorrhage and pain.

Dr. W. H. Parish would like to hear the result in Dr. Baer's case after the lapse of three or four years. Two or three years ago he had reported before this society a similar case, in which, after dilatation by sponge-tents, he had removed a large quantity of endometric growths, and applied nitric acid. The treatment was followed by an apparent cure, which lasted for some months, after the lapse of which the previous condition returned. The same treatment, followed by relief and subsequent relapse, has been repeated several times. Good microscopists have pronounced the growths benign. Dr. Goodell has, however, given it as his opinion that it will ultimately become malignant. Dr. Parish has been gradually coming to the same opinion.

Dr. Beates has treated a woman, æt. 33 years, who suffers from anteflexion of the uterus, men-

orrhagia, and granulations of the endometrium. The microscopic appearance is benign. After treatment by means of the curette and nitric acid, no hemorrhage occurred for four months, the treatment was repeated, a laceration of the cervix was closed, and seven months later the patient became pregnant, abortion occurred at two and a half months, and the granulations and hemorrhages have returned.

Dr. Baer remarked that these cases are very common. They are seen every week at the clinic. They are usually benign, but sometimes become malignant from loss of blood and a run-down condition of the system. Adhesions or some other obstacle to the free return of the venous blood from the uterus may exist, or the ovaries may be diseased; and these causes will bring on the relapse, no matter how perfect the relief may be. In many cases the cause is flexion; the effect is sterility. It is an exaggeration of a purely physiological process. It may be benign in its incipiency, but may become malignant later on.

W. H. H. Githens, *Secretary.*

Editorial Department.

Periscope.

Seventy Cases of Dupuytren's Contraction of the Fingers.

Before the Royal Medical and Chirurgical Society (meeting March 25, 1884):

Mr. Noble Smith read a paper on this subject. Upon examination of the hands of 700 elderly people, 70 cases of indurated and contracted palmar fascia were found. The points to which attention was chiefly directed were: 1. The supposed immunity of females from the affection; 2. The cause of the malady; 3. Its treatment. 1. Among 440 women were found 15 cases of indurated, thickened, and contracted fascia alone, and also 11 cases of well-marked Dupuytren's contraction of the fingers. Drawings of some of these cases were shown. 2. As the disease had been attributed to gout or rheumatism, inquiries were directed as to these diseases, and the evidence was against their being the cause. The majority of the individuals were free from common complaints, and seemed tolerably robust; they were mostly old people, the average age being 73; twelve were over 80. Most of them attributed the contraction to some particular kind of work. The much greater frequency with which the right hand was found affected led one to suppose that use had a material influence. In some cases, the hands had, however, been very little used. Some cases occurred from injuries in which the contraction and thickening were exactly similar in appearance to the others. In many cases the hands were affected symmetrically, indicating some other than a local cause. Contraction of the palmaris longus was almost constantly present, and it was thought possible that this might indicate a condition of nerve-irritation in some instances. 3. With regard to treatment, the author of the paper recommended operation upon the contracted bands of fascia by as few incisions as possible, as opposed to the recommendation that many incisions should be made; the object being to separate the cut parts as much as possible, so that recontraction should be prevented. Cases were recorded which prove the value of this recommendation. It was thought probable that section of the palmaris longus tendon might be beneficial in the early states of contraction.

The President thanked Mr. Smith for his communication, directing attention to a dissection he had brought from the King's College Hospital Museum, showing that the real seat of contracture was in the fascia, and not in the muscles.

Mr. William Adams was very glad to find that more attention than formerly was now being given to this class of cases; for it was not so very many years ago since they were generally regarded as incurable, and amputation sometimes submitted to as the only possible remedy. On May 22, 1877, he had himself brought the subject before the Society, but no attention had been paid to his paper, and the Society had declined to print it among their *Transactions*. Since then it had been published, and he had been glad to find considerable interest aroused. Dr. Keen, of Philadelphia, had taken up the subject, and had collected the largest number of cases in the *Transactions of the Pathological Society of Philadelphia*, in 1882, and added the most complete analysis of the foreign literature. He should be glad to learn from Mr. Noble Smith whether the 440 women he spoke of in his paper were included in the total 700.

Mr. Noble Smith rose at once to say that it was so, and why, if it were so, so many more women had been examined than men. Further, he remarked two classes of cases distinguished among the women, viz., those with "indurated, thickened, and contracted fascia alone," and "also cases of well-marked Dupuytren's contraction of the fingers;" he wished to ask why this division, to which he did not know what importance was thought to attach, had not been carried out among the men. Mr. Noble Smith's cases showed that 10 per cent. of the subjects examined had Dupuytren's contraction. That such was the case with the general population, could not for a moment be supposed, and he had no satisfactory account of how Mr. Smith had selected his cases for examination. He had himself said, when speaking in 1877, that he had seen no true case in a female; since then he had seen six and operated on four. But he still considered it roughly true, as Keen's tables showed, that the disease was ten times as common among men as among women. As to the cause, Dr. Keen thought it largely due to gout, in which he himself agreed; and, as arguments, he would mention that it was frequently hereditary, in several cases for three generations; that it affected the right and left sides about equally, which showed that it was probably constitutional, and not local in origin; that it was found much

more frequently in the middle and upper classes than in the lower; in this it agreed with gout. It was common in the clergy, who never used their hands; in barristers also; but commonest in officers of the army. As to treatment, he could not agree to limiting the number of incisions to two or three, as Mr. Smith suggested. His most successful cases had, as a rule, been those where most incisions had been made, viz., one in which there were eighteen incisions. He quoted details of several cases, and showed many casts of hands, before and after operation. In one of them the operation had been done twenty years ago, and the hand operated upon had remained quite well, though the other had become slightly affected. He thought it very satisfactory that the disease had been brought into notice again, and its curable nature demonstrated.

Dr. Humphry remarked that as to the question of the cause between constitutional gout and local irritation, the truth probably was that it was due to both of them; that local reasons determined this exhibition of a gouty condition. It was generally observed first in the ring-finger, and he associated that with the fact that in handling a stick or umbrella the pressure was felt chiefly in the ball of the ring-finger, as compared with the other fingers. To such pressure its local determination was due. The metacarpo-phalangeal joint was first affected, the others secondarily and less; the palmaris longus probably had very little to do with it, for it was a very small muscle, not having much effect on the fascia, and any effect it might have would influence all the fingers. It was worth notice that similar contractions were extremely rare in the plantar fascia; and that he attributed to the greater and more constant pressure upon the metacarpo-phalangeal joints, keeping them in extension, so that the plantar fascia had hardly the opportunity of contracting that the palmar had. The motion of a toe was hardly ever due to the contraction of the fascia, but to the tension of a tendon. That the ring-finger should be specially affected, was due to the fact that its extensor powers of range were considerably less than in any of the other fingers.

Mr. John Croft admitted that his experience was not large, but in the majority of cases with which he had had to do, he had found a gouty history; but the gouty symptoms were ill-marked, and the limits of gout ill understood. At any rate, that some cases were entirely free from gout was a fact that should be attended to. Mr. Smith's idea that the palmaris longus was affected he thought very improbable, for the first and chief action of that muscle was to flex the wrist, and not the palmar fascia; it was sometimes completely absent, and Mr. Smith had not even shown its presence in his cases. He agreed with Mr. Adams that treatment by multiple incisions was to be preferred.

Mr. W. J. Walsham wished to add his testimony to the value of multiple incisions, which, as he pointed out, were best made in the furrows of the contracted fascia. In the cases under his treatment, he had not met with gout, or been able to distinguish any other cause.

The President observed that what he had heard had reinforced his own impression, that the gouty theory of causation was insufficient. The five old women whom Mr. Smith had brought to the Society that evening had no gouty sign about them. He had noticed with interest Dr. Humphry's remark, that the disease was very rare in the foot; but gout certainly was very much commoner in the foot than anywhere else. Modern fashion was in the habit of attributing more to gout than its just share of the obscurer diseases.

Mr. Noble Smith said that the cases he had examined had been taken from the oldest inhabitants of work-houses. He had asked the medical officers to collect cases where the hands were at all deformed, and had been surprised to find a crowd with deformed hands gathered together, sometimes without any case of Dupuytren's disease. That such cases should be overlooked he thought very probably due to the fact that there was very little inconvenience felt, and no complaint made. Dr. Keen and Mr. Adams had probably chiefly seen cases in the middle and upper classes. He preferred few incisions in treating the contraction, simply because he found a few were sufficient. As to the causation, he wished to point out that he felt himself that the original cause was obscure, and that he had expressed very little opinion of his own.

Unexpected Result in a Case of Strangulated Hernia.

Dr. Geo. R. West reports this case in the *Atlanta M. and S. Jour.* for March, 1884:

"I was called to see A. H., a colored boy, aged 23 years, on the night of December 28, 1883. I went immediately, and found him suffering very much with a strangulated, direct inguinal hernia.

"The boy drove a coal delivery wagon, and was much subjected to strains in loading and unloading. He had not been working the day previous to my visit, but had walked to the country, about two miles; and during the afternoon, about two o'clock, while straining at stool, he felt the bowel escape. He managed to walk home, however, and went to bed, hoping time would cure him; but the pain and size of tumor increasing, he sent for me at eleven o'clock. Before I arrived he had vomited twice with 'purge,' as his old attendant called it, in the vomited matter. His pulse was sixty per minute; he was sweating, though the night was cold, and his general symptoms did not indicate immediate danger. I vainly attempted to replace the bowel, both by position and taxis, persisting in my taxis only about seven or eight minutes. I then gave him the third of a grain of morphia, hypodermically, and left him for an hour. At the expiration of the hour, I returned with chloroform and an assistant, and again attempted taxis with no better success than before. I then thoroughly chloroformed him and applied taxis vigorously, with no better result. I left, with directions to his only attendant to apply hot clothes over the tumor, to repeat them frequently, and to give him twenty drops of laudanum every three hours.

"When I saw him next morning, I was vexed to find my directions had not been carried out, on account of the attendant preferring to sleep.

"Seriously contemplating an operation, I called a consultation. We tried taxis again, and failing, decided against an immediate operation, but

to continue the tr. opii. and warm cloths. This treatment was commenced on the morning of the 29th of December, 1883, and was persisted in until January 1st, 1884, when I gave up in disgust and determined to operate.

"Some may wonder why I persisted so long, but the reason was that at each visit—and I made about three a day during this period—he seemed doing so well, and the tumor growing more soft and somewhat diminished in size. Tuesday morning, January 1, 1884, I operated, using ether. I cut down upon the sac, and, with a probe-pointed bistoury, passed along my finger to the point of constriction, cut the conjoined tendon until everything seemed loose. I then attempted to put back the extended viscus, but was surprised to find it immovable. The adhesions around the bowel, after opening the sac of the hernia, were found to be so strong and numerous, and extending so far down into the scrotum, that to tear them loose seemed certain death to my patient, and I did not have the courage to continue. All the various surgical operations justifiable under the circumstances occurred to me; but I, being young and inexperienced, preferred to close up my incision and let my patient die, as I certainly expected he would. I kept him after the operation for many days under the influence of opium and on a liquid diet. His condition never became alarming, pulse never higher than 110, and temperature never more than 101°. On the 9th of January he took some laxative pills, and on Thursday had a very complete evacuation of the bowels, with no pain or blood. The bowels then became regular, one action a day, and have so continued. Pus had been flowing from my incision for a week, but still the tumor remained about the same size. On Saturday morning, a pimple was noticed at the most dependent portion of the scrotum, which burst during the day and ran freely. At my visit in the evening, I enlarged the opening and drew forth a piece of bowel half the circumference of the gut, and about two inches long. The veins in this piece of slough were enlarged and tortuous. The next day I took some omentum from the same place, and gradually the whole tumor, composed of intestine and omentum, sloughed off and was discharged at this orifice. The patient has fully recovered.

"At the time of the hernia, he was under my treatment for chancroid, which had been touched with nitric acid, but which received no more attention after I began the treatment of the hernia. I am glad to state it has healed nicely of its own accord."

On Opening and Drainage of Abscess Cavities in the Brain.

The antiseptic method of operating and after-treatment has not as yet been fully tested in operations upon the brain. This is natural, for not only have we inherited a just dread of dealing with an organ, the large majority of whose diseases are dangerous or fatal, but, our knowledge of the physiological functions of the brain and of their pathological modifications being extremely limited, we are not in a position to form such an accurate diagnosis as calls for surgical interference. Drs. Christian Fenger and E. W. Lee, of Chicago, in an extremely interesting paper on this subject in the July number of *The American Journal of Medical Sciences*, consider the treatment of traumatic cerebral abscess, and report a case which was successfully treated by opening and drainage.

Bergman, in discussing the treatment of cerebral abscess, unhesitatingly sets it down as an axiom that wherever there is an accumulation of pus, trephining is most clearly and indubitably indicated, for the opening of an abscess in the brain is as necessary as in any other part of the body, and we would add even more so. A correct diagnosis of abscess having been made, the further difficulty presents itself of locating it with sufficient accuracy, so as to be able to find it. A number of cases are on record, in which a correct diagnosis had been made, the trephine also put on more or less at the right place, but the knife or trocar being passed into the brain, nevertheless missed the abscess. Drs. Fenger and Lee show by their case, that this difficulty can be obviated by multiple exploratory aspirations, performed at interstices sufficiently small to prevent any abscess from escaping detection, even if the trephine opening should not have been made at the point of the skull nearest the abscess.

There are on record a large number of cases of cerebral abscess, in which trephining was performed, pus evacuated, and temporary relief obtained; but later relapse followed, and a fatal termination ensued. It is possible, judging from the success the practice has met with in the treatment of abscesses in other situations, that drainage of the cerebral abscess-cavity, with or without washing out, would have saved some of these cases, by preventing the reaccumulation of pus and the continuous infection of the surrounding brain tissue, the acute œdema of which is well known to be, as a rule, the final cause of death. As far as Drs. Fenger and Lee are aware, draining and washing out of cerebral abscess-cavities has heretofore not been tried; that it can be effected and without any detriment to the patient, is shown by their case, the treatment of which they hold strictly conforms to the rational methods of modern surgery in treating abscesses in general; and because of this, and not because their patient recovered, they regard the case as answering affirmatively the question, Is it probable that abscesses in the brain can be treated advantageously on the same principles as abscesses in other parts of the body?

A Case of Universal Erysipelas in a Child Aged Ten Months: with Recovery.

Dr. John Ferguson, of Toronto, thus writes in the *American Journal of Obstetrics*, July 1884:

This case is interesting for the following reasons: In the first place, the entire surface of the child became gradually involved, and, in the second place, as illustrating the value of sustaining treatment.

My first visit was made to the little patient on the 8th of May. I was informed that the disease commenced on the day previous, as a reddish swelling on the right labium. When I saw the patient for the first time, the vulva was greatly swollen, reddish, slimy, and very tender. The

inflammation had also extended on to the pubes and slightly on the lower part of the abdomen.

From this time the disease marched upwards and downwards over the surface of the body, requiring about four days from its appearance at any part till it became nearly normal again in color.

When the erysipelatous inflammation extended to the feet, there was very marked edema. The chest, back and arms, were also taken in turn. The neck and head were next invaded. The eyelids and lips were the last points of attack. In this manner every portion of the entire surface of the body—not omitting the palms of the hands and the soles of the feet, which had a tinge of red—was affected at some time during the course of the disease.

The local treatment consisted in frequently and thoroughly anointing the skin with the following:

℞.	Acid. carbolici,	gr. v.
	Ext. belladonnæ,	gr. xv.
	Ung. petrolei	℥ j.
M.		

Soft cloths were kept next the skin and child loosely and comfortably covered.

The internal treatment consisted in the administration of one teaspoonful every three hours, in water, of:

℞.	Quin. sulph.,	gr. iv.
	Acid. hydrochlor. dil.,	♏xxxij.
	Tr. ferri chloridi,	f. ℥ iss.
	Glycerini,	℥ iv.
	Syr. simp.,	ad. ℥ ij.
M.		

As the child was nursing, no other form of food of any kind was given, nor alcoholic stimulants.

The duration of the attack, from its commencement at the vulva to its disappearance at the eyes and mouth, was fifteen days.

The Treatment of Non-Spasmodic Wry-Neck (Torticollis).

In the *Brit. Med. Jour.*, June 14, 1884, Dr. Burnard Roth says:

The treatment I advocate is divided into three stages:

1. The first is a preliminary education of the patient in performing the usual movements of the neck; viz., flexion, extension, lateral flexion, right and left; rotation on its axis right and left. These exercises are done actively, also against the surgeon's resistance, and by the surgeon against the patient's resistance ("medical gymnastics;" see my article on "Treatment of Lateral Curvature of the Spine," *British Medical Journal*, May 13, 1882). The exercises are done while the patient is lying on his back, sitting, or standing. At the same time, he is shown by the looking-glass how much his head is on one side, and he is taught that he must exert himself to get even a slightly-improved position of the head. This preliminary stage of the treatment need not last more than a week.

2. The second stage of the treatment is tenotomy, under anæsthetics, of the clavicular attachment or of both attachments of the shortened sterno-mastoid muscle.

3. The third stage of the treatment can be commenced as soon as the skin-incisions are healed, that is in two or three days, as the skin always unites by first intention.

The preliminary "medical gymnastic" education of the patient is now most useful; to his surprise, on trying to put the head straight, he succeeds at once, and by daily practicing the previously learned exercises, and others for correcting the lateral spinal curvature, which is nearly always present, he soon learns to hold his head vertically.

At first, even when the head is quite straight, the patient has the sensation that it is on one side, and it takes some days before he is quite satisfied on this point. The third stage need not last more than a fortnight, when the cure will be complete; that is, the whole treatment does not require more than one month, including the preliminary exercises and the tenotomy.

The Poisons Contained in Choleraic Alvine Discharges.

The *London Medical Record*, May 15, 1884, says: Mr. Vincent Richards published in the *Indian Medical Gazette*, March, an account of some experiments on dogs made with choleraic dejections; he failed to obtain positive results. In the April issue he reports positive results obtained by experiments on pigs. In his first experiment he gave to a pig three months old a choleraic discharge which had just been evacuated; the animal became very restless, vomited, and died. In a second experiment the semi-solid contents of the intestine of a pig killed by the alvine discharges of a cholera patient were given to a half-grown pig; the animal was not affected; the same pig subsequently took the alvine discharges of a patient who recovered, but was at the time apparently suffering from the first stage of cholera; the animal recovered, but, in a subsequent experiment, died one hour and twenty-eight minutes after the administration of an undoubted choleraic evacuation. Other experiments seemed to show that the evacuations, if kept more than a few hours, lost their poisonous properties. The administration of fresh evacuations was followed by death in from fifteen minutes to two hours and fifty minutes. Mr. Vincent Richards thus summarizes the conclusions at which he has arrived: 1. That choleraic evacuations, at certain stages of the disease, contain a most virulent poison. 2. That if the poison finds its way into the stomach, it is absorbed and rapidly proves fatal. 3. That the active agent of the poison is not an organism, but of the nature of a chemical compound of a comparatively unstable nature. 4. That it will probably be found to be easy to destroy the power of the poison existing in the evacuations; in other words, to disinfect them. 5. That although the poison decomposes, it might by desiccation retain its powers for some considerable time. Hence, clothes, etc., stained with choleraic discharges, might be a source of danger.

—A solution of gutta-percha in chloroform (four to thirty) is useful to protect the skin over projecting bones, and to prevent bed-sores in wasting diseases.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,

PHILADELPHIA, PA.

THE PRESERVATION OF ANIMAL VACCINE VIRUS IN A LIQUID FORM.

The present methods of preparing and preserving animal vaccine-lymph for medical purposes is not quite the *desideratum* of our profession. One reason is, that there is often found but very little virus adhering to the quills or points. Then again, the manner in which the lymph has to be dissolved is not quite satisfactory. Usually a drop of water is placed on the point or quill, and there left to dissolve the lymph, while the operator is performing the needed scarification. But it actually wants some skill meanwhile, so to balance the point on some article—as a penknife, or the edge of a table, or the back of a saucer, for instance—that the light ivory point neither falls off, nor, assuming a slanting position, allows the dissolved virus to drop off. Some slightly moisten a piece of glass and then rub the point upon it, until all the vaccine-matter is dissolved, and others scrape with a knife the dried virus off the point or quill, and then proceed in the same way. There doubtless are many methods of moistening the lymph on the quill or point, and a little practice enables a physician to make the proper and intended use of the virus; still these various procedures have too many drawbacks. Besides, the lymph does not keep that way any length of time, and there is too much waste of material going on, especially if the operator has but one person to vaccinate at one and the same time. They have also kept fluid lymph in capillary tubes; but as here the virus is but the fluid contained in the ripened pustule, the greater quantity of matter contained in the scab is thus lost, not to mention at all the waste caused by material adhering to the walls of the narrow vessel. It is clear, therefore, that any method promising to be an improvement on the old must be gladly welcomed.

Dr. Chalybaus, in charge of the vaccine institution of Dresden, had met with such remarkable success that he was requested to publish his method of preserving vaccine-virus, and he has done so in a recent number of the *Korresp. Blatt of Saxonia* (6, '84). He proceeds as follows: First, he selects animals which, after examination by

the veterinary surgeon appointed for this purpose by the government, have been pronounced perfectly healthy, and which come from well-known uninfected stables. Moreover, during the whole period of vaccination the animals are twice daily subjected to a critical examination by the same competent authority. The lymph having been obtained from them, the animals are sent to the public abattoir of Dresden and there slaughtered. Not until the post-mortem examination has given undoubted proof of the healthy condition of these animals, is the lymph made use of for the purposes of vaccination. This procedure insures *a priori* healthy virus.

The manner of obtaining the vaccine-lymph is as follows: With peculiarly-constructed pincers the whole pustule, when ripe, is squeezed off, and scraped off the pincers into a mortar made of agate, where it is triturated into a homogenous mass. To about two or three pustules one drop of glycerine—which has been made aseptic by a minute quantity of thymol—is then added, when the lymph thus obtained represents a yellowish, opaque, glue-like, viscid fluid. As little glycerine as possible is employed, but some has to be added, as the lymph otherwise would adhere to the glass-tubes, in which it is preserved. Small capillary tubes have been found not to answer the purpose, as there is too much waste (from material adhering to the tube) connected with this method. Common and rather thick glass tubes are used; they must be large enough to contain a quantity of virus sufficient for ten to twenty vaccinations.

When thus prepared, the glass tubes are placed in a refrigerator for one week. They will then keep for a long time at almost any temperature. The success achieved with this fluid lymph has been remarkable, and with lymph prepared and preserved in the manner described, and kept in a common closet for a period of thirty-four weeks, exactly the same excellent results have been obtained; a proof that the virus does not lose its power by time. No former method allowed the keeping of vaccine-virus for a longer period than at the most three weeks; but Ch.'s procedure permits preservation for at least nine months, and it is probable that further observations will demonstrate the fact that virus thus prepared can be kept in a good condition in any climate and at any temperature for an unlimited time. Whether the freezing for one week, as practiced by Ch., is essential, further investigations will also have to decide.

PROOF OF DEATH.

If most people are afraid of anything, it is of being buried alive. That cases do happen where it is very difficult even for the experienced physician to determine whether a person is really or but apparently dead, without his having recourse to means which, while they would at once settle the dispute, would place life, if it really still existed, in jeopardy, may be judged from the fact that the French Academy some ten or fifteen years ago offered a prize of forty thousand francs for the discovery of some means by which even the inexperienced may at once determine whether in a given case death had ensued or not. A physician obtained the prize. He had discovered the following well-known phenomenon: If the hand of the suspected person is held towards the candle or other artificial light, with the fingers stretched, and one touching the other, and one looks through the spaces between the fingers towards the light, there appears a scarlet red color where the fingers touch each other, due to the still circulating fluid blood, as it shows itself through the transparent, not yet congested tissues; but when life is extinct, this phenomenon at once ceases. The most extensive and thorough trials established the truth of this observation, and the prize was awarded to its discoverer.

When electricity, or rather its application in medicine, came in vogue, it was first thought that it would be a means of deciding whether a person was dead or not. This assumption was based upon the fact of electro-muscular contraction. But experiments soon proved that for one to three hours after death has taken place, and in some cases, where rigidity but slowly ensues, for a still longer period, the muscles of a dead in-

dividual respond as well to the electric stimulus as those of the living being.

Dr. Max Buch now publishes in the *Centrl. f. Neuenhlkd.*, 2, '84, a modification of the above, and what promises to be a reliable and *scientific* proof of death, for thus far no scientific test existed.

While in the living the temperature of the surface over a muscle in the act of, or immediately after contraction, decidedly increases, this increase is utterly wanting in the dead, and even during the time ($\frac{1}{2}$ to 3 hours) in which after death the muscle still retains its contractility. Having placed, therefore, a surface thermometer on the skin, and having waited until the temperature has continued at one and the same height for about five minutes, the muscle just below the bulb of the thermometer is made to contract by electric irritation. If then the column of mercury does not rapidly ascend, we have the most definite and the scientific proof that life is extinct in the body; while if the temperature increases, it is just as certain that there is still life. Under normal condition, the skin for a considerable distance increases by several degrees in temperature, if in the muscle below is caused a powerful electrical contraction; and this phenomenon is also observed in paralyzed limbs; while in the dead nerves, there the production of heat, as induced by motion, has forever ceased.

The method, it is true, has not yet been tested in a cataleptic case resembling death; but it is to be supposed that as long as there is the faintest trace of circulation, so long will increased activity at any part of the body produce a corresponding increase of heat. Apropos, this observation leads us to another interesting fact. It is well known that all over in nature rapid motion calls forth heat, and this is the more apparent the more friction attends the motion. Two stones or two metals rubbed together will soon induce warmth, and the Indians are said to be able to start a fire by the violent friction of two pieces of wood with each other. It is said that no law of nature knows an exception. That may be true, but a dead body surely makes in so far an exception as no amount of motion or friction will elicit the least warmth in the decomposing tissue. But that some mysterious process of heat regulation still is active within the dead body, may be seen from the fact that no matter what the temperature of the surrounding atmosphere, the surface of the body will go on decreasing its own temperature until the state of rigidity is ended and active decomposition commences.

THE MEMORIAL PROFESSORSHIP TO PROFESSOR GROSS.

It is probably known to most of our readers that the Alumni Association of Jefferson Medical College has inaugurated a movement to secure in some medical school the endowment of a Memorial Professorship in honor of the late Prof. S. D. Gross. The professorship will be one devoted to pathological anatomy, to which branch that late eminent surgeon gave so much of his time, with such excellent results.

Certainly, no more becoming monument could be raised to the memory of a distinguished man of science than a chair for instruction in the special branch in which he was particularly interested. We hope, therefore, that this project will succeed, as a testimony to the merits of the eminent surgeon, and as a proof that in the midst of the competition of the living, we are not unmindful of the merits of the dead.

Equally important is this appeal on account of the value of pathological anatomy to the study of our profession. It is one of those branches which are the essential prerequisites to a sound therapeutics, and to an intimate knowledge of the nature of disease. Disowned as useless by the narrow and ignorant teachings of Hahnemann and his followers, it has been the glory of the regular profession to seek and find in pathology the clue to the labyrinth of symptomatology. Nevertheless, it does not lie so close to the practical applications of medicine that it brings in immediate profit to the student. It is well, therefore, that he should be encouraged by such a public recognition of his department as is here proposed.

The chairman of the committee is Dr. D. Hayes

Agnew, and its treasurer is Dr. R. J. Dunglison, to whom contributions may be sent, addressed to Lock Box 1274, Philadelphia, Pa.

This appeal is made not merely to the friends of Prof. Gross, and to the Alumni of the Jefferson Medical College, but to all medical men and enlightened readers who appreciate the immense benefits which his long professional life as a surgeon and a teacher, as a student and a writer, conferred upon the cause of science and progress in this country. Let the answers to this appeal be both prompt and liberal.

Notes and Comments.

Response of Degenerated Nerves and Muscles to Magneto-electric Current.

The well-known reaction of degeneration has thus far been determined only with reference to the galvanic current. Westphal found that in diseases where atrophy of the muscles developed itself in consequence either of myelitis of the cord, or of inflammation of the motor-nerves, the muscles reacted in a peculiar, abnormal manner to the galvanic stimulus. Usually in healthy muscles the contraction is stronger on closing the current with the kathode, or expressed by a formula: K. C. C. (Kathode closure contraction); A. C. C (Anode closure contraction). But in the diseases mentioned the reaction of degeneration shows A. C. C., K. C. C.

Eulenburg has recently investigated the reaction of degenerated nerves and muscles to the Faradic stimulus (*Neurolog. Centrlbl.*, 1884, 5). He found in patients with quantitative changes of electric excitability the irritability for magneto-electric currents to be equal to that for Faradic (volta-electric) currents. The same happened three times in four cases evincing the galvanic reaction of degeneration (Deg. R.) But in a case of slowly improving rheumatic facial palsy, he noticed at a time when the Faradic reaction could just be traced in the nerve, on magneto-electric stimulation, undoubted motion, though weak and slow in the nerve, and also in the muscles of the face, which had not evinced the least Faradic response. The number of turnings necessary on the diseased side exceeded those needed for the healthy side from four to eight times. The difference in the reaction is probably based upon the longer duration of the single electric discharges in magneto-electric currents, for we know that in a certain stage of its degeneration the muscle reacts on stimulants of longer duration. In the case reported, after a short interval of exclusive response to the magneto-electro current, the excitability returned also for the induction-current.

It is probable that a greater number of observations may prove the utility of the application of all three currents for diagnostic puposes. For instance, a muscle may show deg. R. with the galvanic current, no response to the Faradic, but a mild excitability on application of the magneto-electric current. Whether this fact will lead to therapeutical results, experience and further researches will have to demonstrate.

Subcutaneous Injections of Iron.

At the time when dialyzed iron was still in vogue, the profession hoped at last to have found a preparation of iron which could be employed in hypodermic injections without causing violent irritation. Experience proved not only that dialyzed iron really was not such a drug, but also that its effect was as nothing; its percentage of iron being too small, considering that it is just in the worst cases of anæmia where we find great sensitiveness of the stomach, forbidding the internal employment of iron, it will not astonish us that experimenters have since continually employed their time to discover a preparation of iron that could be used subcutaneously.

Dr. Glaevecke (*Arch. f. Exp. Path.*, etc., xvii., p. 466,) has at last found that the citrate of oxide of iron is the best of all organic and inorganic iron salts that the materia medica offers for that purpose. The oxydulated sulph. of iron can be made absorbable by the addition of two to three times its quantity of citrate of sodium, while peptonized iron is badly, and ammoniated sulphate of iron not at all absorbed. The secretion takes place mainly by the kidneys, in less quantity by the liver; it commences by the urine within fifteen minutes, reaches its maximum within two to four hours, and is ended within twenty five hours. The iron always appeared as oxyd- and oxydul-salt, while the iron met with in the bile always was the oxyd-salt. The liquor sanguinis and the ascitic fluid found in rabbits always contained the iron; the aqueous humor never did. G. has formed the conclusion that the iron is retained in the blood as an albuminate, but is partially reduced to an oxydul-salt in the urine alone.

For therapeutical purposes, G. tried the oxydized citrate of iron in ten patients. The result was as expected from an iron-salt, thus absorbable.

The doses for adults is about half a grain, for children grenerally one-fourth; it is best employed in a ten per cent. solution, which must be clear and not older than a month. Certainly this all refers only to the hypodermic method of its employment. Larger doses may cause symptoms of intoxication, consisting of nausea, within twenty minutes increasing to vomiting—the best morbid proof of the absorption of the remedy.

In twelve case of nephritis the injections were made with the view of diminishing the quantity of albumen excreted; but the effect was nihil.

Cause of Conjunctivitis in the New-Born.

Authors have been divided regarding the causes of inflammation of the eyes in the new-born. Some contended that only the specific virus of gonorrhœa could produce the conjunctivitis, while others insisted that under certain conditions the common discharge of the vagina during the passage of the child may induce the eye-disease. A solution of nitrate of silver, four grains to the ounce, one drop passed three times daily into the inflamed eye, has always been considered a very efficient remedy, especially if early applied, *i. e.*, before irreparable damage has been done by the inflammation. Ice-water compresses greatly accelerate the cure.

Since the germ-theory has found so many adherents, and considering the infectious nature of the conjunctivitis, mild solutions of corrosive sublimate ($\frac{1}{10000}$) have also been used, and with such a remarkable success as to prove almost beyond a doubt the zymotic nature of the eye complaint.

A German physician, P. Zweifel, has recently instituted a series of experiments with a view of determining definitely the mooted question. Z. introduced into the eyes of six children, perfectly normal, lochial secretion, which he had procured from healthy mothers, of whom there was definite proof that neither they nor their husbands had ever suffered from gonorrhœa. The result was very satisfactory, not the least inflammation of the eyes ensuing. Though the number of the experiments is rather a small one, Z. draws the conclusions that the specific virus of gonorrhœa is essential may be simple, compound, or comminuted. In for the production of ophthalmia neonatorum.

The editor of the *Centrlbl. f. d. Med. Wiss.*, May 21, 1884, p. 368, while reporting the observations of Zweifel, remarks that the experiments should be repeated, and that in every case of genuine ophthalmia neonatorum the presence of gonococci should be inquired into; for, as well-known, these micrococci have been met with in the discharge of the specific urethral disease.

Chloroform Syncope Treated by Reversing.

As a valuable hint, we note that in the *Brit. Med. Jour.*, Dr. Albert I. Garland relates a case wherein he began to operate on a lady, aged forty-one, for the removal of a scirrhus of the mamma. After examination of the heart, which was found normal, they commenced administering chloroform; but the cardiac action becoming very excited, a mixture of chloroform and ether was used. She was some minutes going under the influence, but there was scarcely any struggling, and the pulse was full, though jerky. He had not finished the incisions round the tumor when she suddenly became livid and the pulse ceased. Artificial respiration was begun, the tongue drawn forward, and strong ammonia applied to the nostrils, without avail. He immediately jumped on the bed, and seizing her legs, raised the body, allowing the head to touch the bed. In a few seconds, the color returned to the lips, and the pulse to the wrist. Artificial respiration was soon resumed; hot water applied to the region of the heart; and she became sufficiently conscious to speak and to swallow some brandy and ammonia, soon, however, relapsing, pulse and respiration ceasing again. He again reversed, with the same result; but in a short time the syncope returned, and after applying the battery without success, he again reversed, and this time with a satisfactory result, as he was enabled, by the use of the battery and ammonia, to establish reaction.

He considers his case worthy of record, as the successful termination was clearly due to reversing the body, it being impossible, apparently, to stimulate the nerve-centres by any other means; and it is a method of treatment which, he thinks, is not used so often as it deserves to be, judging by the reports of such cases, as he only remembers having seen it mentioned in one instance, and it is one so easily and quickly adopted.

Neuralgia Caused by Exostosis.

A lady suffered from intense neuralgia in the region of the second and third branches of the trigemini; especially during mastication, the pain in the right superior maxillary bone was so violent as to force the lady to chew only on the left side of her mouth. These neuralgic attacks, which were really very severe, had existed for several years. As the patient had besides been several times the victim of inflammation of the right external meatus, Dr. Moos, who attended her, and who reports the case in the *Berl. Kl. Woch.* 8, 1884, inquired further into the history of the neuralgia, and found that it always seemed to

start from a definite point in the same meatus. Ocular inspection revealed the presence of a small exostosis of the size of a split pea in the meatus. There were two other exostoses in this passage, both anterior to the one first-mentioned, but Moos soon discovered that the posterior one was alone sensitive. This exostosis was, therefore, removed with the straight chisel, and the pains at once ceased, and have since, nearly ten months, not returned. As a remarkable fact may be mentioned, in conclusion, that while the pain specially affected the second branch of the nerve, it started in the third, upon which the pressure was exerted by the exostosis.

It is not in all neuralgias that we can find a starting point. But we should always look for one; and if determined, it will generally be observed that some new growth exerts pressure on the nerve. This new growth may either be a tumor or the product of inflammation, as thickening and swelling of adjoining tissues, or accumulation of matter, as is frequently noticed in cases of a carious tooth, where a small abscess forms at the root of the tooth and causes the neuralgia by tension, *i. e.*, pressure upon the nerve.

Carbolic Acid Injections of Piles.

Dr. Wm. F. Fleet writes to the *Therapeutic Gazette* for May, 1884, that he has been using the hypodermic treatment for piles for the past four or five years, and with universal success. The second case he had was a physician from Middlesex county, Virginia. He attacks only one pile daily, and where there are five or six piles, it sometimes happens they are relieved by injecting every alternate one; but it is safest to attend to each one in turn, and thus effect the entire removal of all. In this doctor's case he had had a bad prolapsus of the rectum, and had used sundry instruments and appliances to remedy his trouble, but none of them afforded him any relief. The rectum was promptly relieved at the last operation, and he returned home at the expiration of a week a sound man, so far as his piles and prolapsus of the rectum were concerned. He reported about twelve months afterwards as still relieved, and no return whetever of hemorrhoids or prolapsus. In very large tumors, it may be necessary to inject them two or three times before the circulation is cut off. He varies his prescription a little, according to the case for treatment:

℞.	Carbolic acid crystals,	℥ii.
	Pure glycerine,	℥ss.
	Fluid ext. ergot (fresh),	℥iii.

M. and use in syringe from 5 to 6 minims at each injection. He sometimes adds a fractional part of a grain of tannin, if there is not a prompt coagulum in the pile.

Influence of Narcotics on the Space-Sense of the Skin.

At the second Medical Congress, held April 20, 1884, at Wiesbaden, Dr. Rumpf gave an interesting lecture on this subject. He had experimented with a number of drugs, and made the following observations:

Within from six to eight minutes after a hypodermic injection of $\frac{1}{6}$ to $\frac{1}{4}$ of a grain of muriate of morphia, a decided diminution of the space-sense was observable over the whole body, reaching within one hour its maximum, but still noticeable after the lapse of twenty-four hours. Near the place of injection the morbid appearance was by no means greater than at any other part of the body; the peripheral irritation, besides being a minimum, and simply due to the presence of a salt solution. Chloral hydrate exerted much less influence in this respect; alcohol reduced the sensibility especially in the lower half of the body; bromide of potash had a very great effect; extract of hyoscyamus a very small one; cannabinum tannicum diminished the sense of space decidedly; while caffeine was the only drug which doubtless increased it.

These observations permit a two-fold explanation. There either exists a special centre for the sense of space, or some of the conductory fibres of common sensation must possess the special faculty of conducting only space-impressions. Strictly limited morbid lesion can alone decide this mooted question.

Chancre of the Tonsil.

Dr. R. W. Taylor concludes a paper on this subject in the *N. Y. Med. Jour.*, May 24, 1884, by giving the following diagnostic points:

1. The details of the mode of infection, either from syphilitic sores, primary or secondary, chiefly about the mouth or face, and mostly by kissing; from infection by some article, such as a nursing-bottle, cigar, pipe, cup, or the like; or from indulgence in bestial practices.

2. The slow, unilateral development of the chancre, with corresponding gland and ganglion enlargement, so well marked.

3. The limitation of the lesion to the affected side.

4. The difficulty in deglutition, and even pain, which is referred to one side.

5. The history of the evolution of the syphilis,

the absence of chancre from other parts, especially the genitals, and the much less indurated condition of the ganglia seated elsewhere. Those that are seated at a distance may not be affected until near the date of the evolution of secondary manifestations.

The Induced Current in Parturition.

Before the Obstetrical Society of London (April 2, 1884,) Dr. Kilner read a paper on this subject. The effects of the current were the relief of pain, prevention of fatigue and *post-partum* hemorrhage, equalization of the pulse, increase in frequency and strength of the uterine contractions, and the prevention of vomiting. The pain from stretching of the vulva was, however, not alleviated by it, nor did it to any extent relieve pain in cases of instrumental labor. The author now employed the coil in nearly all cases. In about three hundred cases, *post-partum* hemorrhage only occurred twice. The coil sometimes failed to increase uterine contractions when most needed. After its use for an hour or an hour and a half, it exercised its sedative action, and no longer increased the contractions. In some cases it produced violent and almost continuous contractions. In one case a contraction lasted fifteen minutes. No prognosis with regard to these points could be made. It had no effect in diminishing after-pains. It generally prevented or stopped vomiting.

Adenoma of the Liver.

A patient suffered from pain in the right hypochondriac region and a general decline in health. A soft circumscribed tumor was discovered in connection with the liver. The post-mortem examination showed a tumor in the greatly enlarged right lobe of the organ. The new growth had its own capsule, and was perfectly separated by it from the neighboring areolar tissue. Its interior consisted of a cavity of the size of a child's head, and filled with blood. The microscope proved the tumor to be an epithelial new formation, whose elements were arranged similar to the type met with in tubulous glands, and which, besides being in direct connection with the bile-ducts, was filled with blood.

Take Care of Patent Purgative Pills.

A man, æt. 46, had suffered for a long number of years from tonic spasm of the stomach (tonic gastralgia). He at last died in such an attack. Drs. Dujardin-Beaumez, and W. Œttinger, who report the case in the *Union Med.*, 1884, pp. 15 and 18, found dilatation of the stomach to have been the cause of the spasms, and they agree with Kussmaul, that this morbid condition was induced by rapid thickening of the blood and the drying of nerves and muscles, due in this case to violent diarrhœa following the use of so-called Swiss pills, a patent medicine greatly used by the people in Germany and France.

We have had in our charge two cases, in whom the first symptoms of gastralgia developed itself after the use of patent purgative pills. Sapienti sat, or as a German proverb says: Wer nicht hören will, muss fühlen (who don't want to listen to advice must suffer pain).

Jequirity.

This drug has been so highly vaunted, and so much discussion has taken place as to the nature of its active agent, that we feel bound to keep our readers informed of all that is published on the subject. Therefore we note from the *Jour. Am. Med. Ass.*, May 17, 1884, that Dr. T. E. Murrell read a paper on this drug before the Arkansas State Medical Society, which thus concludes:

1. The specific action of jequirity depends on some property peculiar to the bean itself, and not to the bacteria, which accidentally develop in the infusion.

2. There is a preservative principle in the bean which resists decomposition to a remarkable extent.

3. The infusion of jequirity is inimical to the successful development of bacteria, and restrains their multiplication.

New Method of Coloring.

In the *Fortsch. d. Mediz.*, II. No. 6, we find the following new method of coloring for the central nervous system: The slices of brain or spinal cord are kept for one or two hours at 35 to 45° C. in a solution of hæmatoxylin, then washed in distilled water and decolorised in a borax-ferro-cyanide of potash solution. When the slices have been left in this last solution for a sufficiently long time, the difference in the appearance of the gray and white substance becomes very great; besides, this method has the other advantage of showing plainer than any other the course of fibres in the gray substance.

Radical Operation for Congenital Hernia.

In his communications from the Royal Surgical University clinic in Berlin, Dr. A. Zeller (*Centrlbl. f. d. Med. Wiss.*, 1884, No. 21, p. 367), reports the full history of six operations, which disprove

the correctness of Kraske's opinion, that in cases of strong adhesion of the seminal cord and its vessels the radical operation for scrotal hernia could not be performed without simultaneous castration. In three cases the hernial sac was partially extirpated, and the hernial neck later closed by internal suture, according to Czerny's method. In two of the cases a permanent radical cure was the result. Like other surgeons, Zeller also insists upon his patients wearing a truss for a certain period of time after the operation has been successfully performed.

Z.'s reports are of paramount importance, as they demonstrate the feasibility of a radical cure, even under the circumstances mentioned, without castration being necessary.

Cinnamon Bark for Tooth-Ache.

In the *North Carolina Med. Jour.*, April, 1884, Dr. J. R. Irwin writes that one of the best and most pleasant things that can be used to relieve this painful state of the dental nerves, is chewing cinnamon bark. It destroys the sensibility of the nerves and suspends the pain immediately, if the bark is of good quality. After repeated trials, and in different cases, he is convinced that it is generally as efficacious as any of the other remedies, suggested for odontalgia, and not attended with the unpleasant consequences of creasote, carbolic acid, etc., which relieve the pain, but leave the mouth as sore and painful as the tooth was previously, though these results are usually due to carelessness in using.

Occurrence of a Rare Human Tapeworm (Tænia Flavopunctata).

Dr. Joseph Leidy, of the University of Pennsylvania, describes in the *American Journal of Medical Sciences* for July, 1884, the tænia flavopunctata, a rage human tapeworm, which has now been observed for a second time, both cases occurring in this country and infesting children. It is not improbable that the species is more common than the observations would warrant us in believing, for from the smallness of the worm and the generally prevailing ignorance of the distinctions in the more common species, it might readily be passed for immature portions of these.

How to Prepare a 1 to 1,000 Solution of Corrosive Sublimate.

In view of the extensive use of this agent as an antiseptic, it will be interesting to note that Sir Joseph Lister writes to the *British Medical Journal* (May 24, 1884), that one drachm by weight of a solution of one part of corrosive sublimate in one and a half parts of glycerine contains two-fifths its weight, or twenty-four grains of the sublimate. This, multiplied by 1,000 (the proportion of water required), gives 24,000 grains, which is very nearly three pints. It is, however, much more convenient to use fluid measure than weight, and a fluid drachm of glycerine solution referred to requires four pints of water to produce the 1 to 1,000 solution.

Correspondence.

Alkalinity of the Stomach.

Eds. Med. and Surg. Reporter:—

E. Chenery, M. D., in his very instructive answer to G. W. S., gives us information as to the cause of certain gastric disorders which it would be well to impress upon the mind of every medical practitioner. That some of the most intense pain which we have to encounter is caused by irritability of the stomach, which is due to the neutralizing influence of the regurgitated alkaline bile, is a fact of which my experience has for several years since been very convincing. Dr. C. has put the cause of these disorders very plainly to the readers of the Reporter; and if it can be deemed admissible to add further confirmation to the facts set forth by your distinguished correspondent, I will, by your consent, relate briefly the following cases, with the hope of adding by way of experience to the arguments already produced.

Case 1. Mrs. B., a young lady of good constitution and regular habits, came into my care June, 1881. She had been suffering the two years previous to this time with supra-orbital neuralgia in its most intense form, the paroxysms had grown more frequent and intense from the beginning, and the last six months previous to the time I was called to see her she had been confined to her room and bed more than half of the time. Her appetite was poor, her strength and flesh very much reduced, bowels constipated, tenderness and frequent griping pains in pit of the stomach, constant nausea during the paroxysm, which would usually terminate with bilious vomiting. She informed me that as soon as she could vomit freely she would get relief; the tongue was very red, papilla prominent. Morphia had been given with relief in the start, but latterly failed to check the pain, which was the most agonizing and intense I ever witnessed. I considered the neuralgia symptomatic of the gastric disorder, and directed my treatment to that organ. Muriatic acid, pepsin, and tinc. ipecac, were given for the stomach, two drops each of fl. ext. nux vomica and belladonna were given once daily, and a mild cathartic occasionally to overcome the constipation.

This treatment was continued, with slight variations, as symptoms required, for two months. Since then my patient has suffered very little with neuralgia or trouble with her stomach. With a well-regulated diet, consisting largely of

fruits, she tells me she enjoys excellent health; but if she allows her bowels to become constipated, her old symptoms return, in a modified form.

Case 2, æt. 30, male, called me to his relief on the night of April 12, 1884. I found him suffering very intensely with a griping pain in the pit of his stomach. Gave morphia, and left him for the night. On the following day ascertained the following history and conditions: Since November, 1883, has had recurring attacks of gastric pain of a very severe character at intervals of from one to six days, the pain lasting from a few minutes to several hours; the bowels slightly constipated, for which blue pill had been given in purgative doses at intervals, when it seemed to be indicated, and it would be followed by marked relief for a few days, but did not seem to exert any preventive influence over the recurring pain, as the attacks had continually occurred more frequently. The tongue was broad, relaxed, and very red. Appetite poor; frequent gastric disturbances after eating. On several occasions the sclerotics and cutaneous surface presented a well-marked jaundiced appearance, which led his attending physician to suspect biliary calculi, for which he had been taking treatment previous to the time I first saw him. I considered the case as one of irritability of the stomach due to the destruction of the natural acids of that organ, and prescribed muriatic acid and bitter tonics to restore the gastric functions, and a pill composed of small doses of nux vomica, belladonna, and podophyllin, to relieve constipation. The gastric pain has not returned since the first night I was called to treat it, and the patient's general condition has steadily improved, and he now feels better than he has for a year, and is taking no medicine at all. I have treated a number of cases somewhat similar to those related on the same principles, with like results, and feel thoroughly convinced that the theory is correct and the treatment successful.

I will say, in conclusion, that I would like to hear from others on this subject.

J. H. Moore, M. D.

Mt. Sterling, Ky., July, 1884.

Laryngo-Tracheotomy, After Apparent Death, with Recovery.

Eds. Med. and Surg. Reporter:—

June 16, at 5:30 p. m., I was called in great haste to the dental rooms of Dr. V. B. Pool, where I found that while extracting a bicuspid tooth from the mouth of his little six-year-old niece, the tooth slipped from the forcep and passed into the throat. I found the child with very difficult breathing. I immediately passed an instrument into the œsophagus to see if it had passed there, and found that it had not. I then made examination sufficient to satisfy myself that it had passed into the trachea, and told the doctor and mother that the tooth would have to be cut out. I immediately called counsel. The counseling physician thought it not practicable to operate, as he thought the tooth had passed into one of the bronchi; also, he would not operate without using chloroform. Not being satisfied with his decision, I immediately sent a messenger for Dr. J. H. Hutchins, who was four miles in the country. The doctor arrived one hour and a half from the time I first saw the child. Just as Dr. H. entered the room, the child collapsed. Pulsation and respiration ceased; but Dr. H. thought we had better operate; so I obtained consent of the mother, and we immediately operated, Dr. Hutchins using the knife. An incision was made exactly in the middle line, extending from just above the cricoid cartilage, about two inches toward the sternum, the subcutaneous tissues were carefully cut through, avoiding the inferior thyroid vein. The trachea being reached, an incision was made severing part of the cricoid cartilage, and the two upper rings of the trachea. Fortunately, the incision was made right over the tooth, which was immediately removed, and work began to try and resuscitate the child. Artificial respiration was kept up for about twenty-five minutes, when the child gasped. We continued work for about five minutes, and had the satisfaction of seeing the child breathe through the opening. There was but little hemorrhage. The wound was left open for twenty minutes, until all hemorrhage had ceased. We then introduced three silk sutures through the skin, leaving the incision through the trachea as when it was made. The child was then placed in bed, and carbolized gauze placed over the wound. When the child would attempt to speak, for about four hours afterward, the air would pass through between the sutures. She slept well that night, and on the following morning drank some milk, and twice through that day took liquid food. From the time the operation was performed until the child was discharged, there was no rise in temperature. The wound healed almost entirely by first intention. In five days, at which time the sutures were removed and new adhesive strips applied, the child had recovered complete control of the voice. During the operation the child did not move a muscle, and for twenty minutes afterward there were no signs of life.

Now, the question comes in, When is it too late to operate? and how long should artificial respiration be kept up, and other means to try and restore life?

E. M. Keys, M. D.

Hampton, Iowa.

The Dictum of Authority.

Eds. Med. and Surgical Reporter:

The following case is only one amongst many others of degeneration of tissue, and in itself of no particular value; but as illustrating the wisdom attached to position, it is, I think, worth a good deal.

Mrs. ——, 51 years of age, of healthy parentage, mother of several children, was confined with her last child some six years ago. There was nothing remarkable in her confinement, and her health was good as usual till within the last year, when she complained of pain in lower abdomen, particularly in left inguinal region. On the 22d day of last February, Dr. ——, her family physician, was called to see her, and after a few visits, regarding the case of much gravity, he asked for a consultation, which was had, and a cancerous tumor diagnosed, was touched per vagina and rectum. The case still growing worse, another consultation was had with another physician, and the former diagnosis confirmed. As medication

was still futile, Professor ——, of considerable surgical celebrity, and of a neighboring city, was called to see the case. His opinion, after careful exploration, was that her last pregnancy was twins, one dying during gestation, and somehow becoming encysted and retained at parturition. Then quietly in the lapse of years burrowing its way through the wall of the uterus into the abdomen, and without any constitutional symptoms whatever(for this woman was a farmer's wife, doing the work of a farmer's wife till last February), finding its way low down into abdomen, projecting into pelvis, and misleading the attending physicians and his consultants with the idea of a tumor. And so sure, says the family physician, was the Professor of his diagnosis, that he only failed to operate then and there for want of instruments.

Now another consultation was had, with one of the attending physician's former consultants, *when they too could outline a fœtus, touching fontanel and orbits, and perhaps a rib.*

Well, this poor woman died, and on the 22d of last May a post-mortem was held in presence of eight of the neighboring physicians. The case had become notorious, hence this array of professional talent. On opening the abomen we found an enlarged and degenerated left ovary, much plastic matter had been effused, binding ovary to upper portion of rectum, and by pressure so obliterating cavity of gut as to prevent a proper motion of bowels. L. G. Harley, M. D.

Apple Creek, Ohio, June 3, 1884.

Muriated Ingluvin.

Eds. Med. and Surg. Reporter:—

I have been using for a long time two preparations of ingluvin, and have them prepared in the following manner: I order four ounces of the dried lining membranes of the chickens' gizzards to be reduced to a coarse powder, and macerated for twelve days (in a wide-mouthed, glass-stoppered bottle) in twelve ounces of diluted muriatic acid, made of the chemically-pure acid, and agitated once every day or two until the end of the twelve days. It is then allowed to settle, after which the liquid is carefully and entirely drained from the membranes and kept in a glass-stoppered bottle for use. This I call *muriated liquid ingluvin*, and it possesses a strong acid odor and taste, and presents a dark appearance. It keeps well, and I administer it in ten to twenty-drop doses in a half wine-glass of water before each meal; and of all preparations, I know of none that will change so quickly that condition of the stomach manifested by a habitually white-coated tongue.

After the liquid is drained off, I have the remaining macerated mass dried upon a sufficiently-heated slab or spread upon paper to be dried in the open air; and when well dried, I have it reduced to a fine powder, and also kept in a glass-stoppered-bottle. This I call *muriated powdered ingluvin*, and it likewise possesses a strong acid taste and odor, and a dark appearance. I give this in five to ten-grain doses, singly or in combination with bismuth, quinine, or iron, when the state of the digestive organs demands such combinations. These preparations are readily and cheaply made and are pure and reliable. I use these with the greatest relief to my patients in all the various forms of the interruptions of the appetite caused by debility of the stomach and insufficient secretion of the gastric juice, causing what is known in ordinary language as chronic indigestion and atonic dyspepsia. J. B. Johnson, M. D.

Washington City, D. C.

News and Miscellany.

Hygiene in Domestic Service.

A foreign exchange says: Every practitioner must have remarked the commonness of a certain type among the patients who come to consult him from the ranks of domestic service. We have chiefly in our eye female servants, for these especially exhibit the condition to be considered, though men and boys also, sooner or later, suffer in a similar way. The fagged and irritable heart, the watery but spastic puise, atonic dyspepsia, and *malaise*, even apart from the evidence of a pasty skin and history of hard house-work, suffice for the diagnosis of anæmia. It is very common to find that the subjects of this condition have but recently come up from the country. They have exchanged the fresh air, regular hours of work and rest, and plain wholesome fare of their former homes or service, for the late work, the early waking, and the small unventilated sleeping-room of a city mansion. The relation between cause and effect is obvious. Hygiene is ignored and health suffers. What, then, is to be done? It is easy to point to the evil, but more difficult to devise its cure. We are convinced, however, that much could be accomplished by a reasonable exercise of common sense on the part both of masters and servants. More space, air, and sleep are required. By means of these the frame will be rendered fitter to meet and overcome the generally moderate fatigue of domestic service. With regard to air-space in servants' bedrooms, it should not be very difficult to allot a minimum of 800 cubic feet per individual. Less than this must lead to impairment of health. Ventilation can, as a rule, be maintained even in our capricious climate, if servants can be taught that the window may be kept slightly open at the top without danger from cold. A room without free communication with the outer air readily becomes impure, and is unfit for habitation; a window is a necessity. Seven hours sleep for men, and eight for women, are generally admitted to be no more than essential, and might, with but very moderate forethought, be allowed by masters and mistresses to their domestics. We have not spoken of recreation. It is often difficult alike for servants and for comparatively independent persons to make due provision for this important factor of health. Something has, no doubt, been done by timely holidays. Measures like these which we have suggested must, if adopted, help and not hinder work, and must increase the well-being and just contentment of that large class on which every other class is, in so great a measure, dependent.

—Latin is a "dead language"—when an inexperienced drug clerk fools with it.

The Berlin Polyclinic.

Our correspondent, Dr. Ludwig Loewe, of the Berlin Polyclinic, writes us about this institution:

"Clinical courses, comprising all the different special branches for practical physicians, are held every month in the Polyclinic at Berlin (Germany), Cpalstrasse 30. The courses always commence on the first week-day of the month. They last a whole month, and are held every working day.

"The number of participants is limited to six for every course. Should more than six apply for the same course, an extra or parallel course will be formed.

"To all those physicians wishing to perfect themselves in a special branch, the opportunity is given to serve three months as assistants in that particular branch. Those gentlemen having served as assistants will be allowed in appropriate cases to conduct the extra or parallel courses.

"We intend to elevate the Berlin Polyclinic to an international medical school for the improvement of physicians of every country. In order to have the courses conducted in foreign languages, assistantships will be conferred also to foreign physicians."

What Caused Hunter to Ligate an Artery for Aneurism.

The *College and Clinical Record* notes that none of the books tell how John Hunter was led to originate the operation of ligation for popliteal aneurism. Prof. Chapman gives the facts as follows, and in parenthesis some strong words about the anti-vivisectionists: "Hunter, finding the 'velvet horns' of a deer to be abnormally warm, tied the carotid artery; in a few days he was astonished to find the horns were as warm as ever. He at first supposed that he had tied the wrong vessel, and cut down on his ligation only to find that he had not made a mistake in identification, and that the carotid was still occluded; further investigation showed that a collateral circulation had been established—a thing practically unthought of before. Deductions from this experiment were what led him to believe that the femoral artery could be tied without exsanguinating the limb, and he caused the experiment to be performed on a live dog, with success. After these experiments he performed the operation on a coachman, in 1787, in St. George's Hospital, on the walls of which still hang the deer horns, which, in John Hunter's hands, were the means of incalculable good to mankind."

The Power of a Board of Health to Prevent the Keeping of Pigs.

A Board of Health in an English town not long since passed a regulation forbidding the keeping of any pig within fifty feet of a dwelling-house. This naturally caused a small tempest among the Irish population, and a suit was brought to restrain the Board from enforcing the regulation. In defence to this suit it was alleged that they had power to prevent the keeping of animals on premises where they would be injurious to health, and that they had not exceeded their powers. The court did not take this view, however, but decided that the regulation was too broad, and could not be sustained.

Urinary Test Papers.

The firm of Messrs. Parke, Davis & Co. have devised a very neat case of urinary test papers, put up in convenient packages for carrying in the pocket. They are prepared according to the method proposed by Dr. Oliver, of England. (Price, 50 cents by mail.) We can recommend them as the most convenient that we have anywhere seen. They are accompanied by a test-tube and dropper, in a well-constructed box, containing a small pamphlet of instructions sufficient to acquaint the tyro with the mysteries of this simple yet extremely important diagnostic procedure.

The Beef Peptonoids.

Among recent food preparations, those which are called the beef peptonoids have taken a high rank as a form of easily-digested nitrogenous food. They have received praise as remarkably nutritious and as readily preserved without change, from such chemists as Attfield, of London, and Stutzer, of Bonn. Their high value depends upon the great quantity of digestible albuminoids which they contain.

A Useful Ophthalmic Test Card.

A new test card for myopia, hypermetropia, and astigmatism, has been devised by Dr. Wm. S. Little and lithographed by J. W. Queen & Co., of this city. It contains a number of novel features, and greatly simplifies the diagnosis of these conditions. A descriptive circular of instructions is added.

Items.

—In Calcutta during the month of April there were four hundred and eighty-six deaths from cholera.

—A child recently born, in West Troy, has three perfectly formed legs, the third protruding above the right hip.

—The Mississippi Valley Medical Association (Tri-State) will hold its next meeting in Springfield, Ill., in September, 1884.

—Prof. Gross never operates on menstruating women, if it is possible to avoid it. Oozing is apt to occur from the wound.

—In a letter to the *London Lancet*, April 26, five drops of tincture of cantharides is recommended for incontinence of urine.

—Dr. J. Sutherland, of Bedeque, P. E. I., reports a case of triplets. The children weighed 6, $6\frac{1}{2}$, and $7\frac{1}{4}$ pounds respectively. Mother and children all doing well.

—A favorite prescription of Prof. Da Costa, for the constipation of plumbism, is one drop of croton oil made into eight pills, of which one is given two or three times a day.

—Mr. Charles Adolph Würtz, the distinguished French chemist, whose name is particularly asso-

ciated with the progress of organic chemistry during the last half century, died very suddenly on the 12th of May last.

—Dr. W. C. Jarvis, of New York, recommends the trioxide of chromium, or chromic acid, for the removal of intra-laryngeal growths, especially papillary. It is best employed fused on the point of a probe, an instrument to act as a protector and guide may be used with it.

—Regarding skull fractures with great depression or comminution, Prof. Brinton teaches that the operation is not to be delayed for symptoms to appear. The operation *per se* is not dangerous, and brain symptoms have come on twenty years after the accident. This agrees with Prof. S. D. Gross's opinion.

—Dr. William H. Lopp, of Columbus, Ind., in his paper on Quacks and Quackery in Indiana in the Transactions of the Indiana State Medical Society of 1883, relates "that one of the bogus M. D.'s, in a case of erysipelas, stated to the patient that it was called 'airesipelas' because it traveled in the air—therefore was catching.

—At a recent meeting of the Philadelphia County Medical Society, Dr. Carl Seiler called attention to the value of tincture of benzoin in the treatment of chapped hands and frosted feet. He has used it in a number of cases with much success. It is applied by simply painting it on the skin. The stocking may be prevented from sticking to the feet by rubbing some oil over the benzoin.

OBITUARY NOTICES.

DR. BENJAMIN WILLIAM DUDLEY.

At a meeting of the physicians of Lexington, Ky., held at the office of Drs. Skillman & Scott, the following was unanimously adopted:

"His professional brethren having heard, with feelings of deep regret, of the death of Dr. Benjamin William Dudley, which occurred in Lexington on Thursday, July 3, 1884, at ten o'clock, consider it eminently just and proper thus publicly to give expression to their esteem of him, and offer a tribute to his memory.

"Dr. Dudley bore the name, and was descended from a family illustrious in the annals of Kentucky surgery; and his being taken away at the age of forty-six years, in manhood's very prime, in the midst of professional success, blighted high hopes, and put to an untimely end a career of usefulness and distinction.

"After graduating at the Medical College of Keokuk, Iowa, and living a short time at Hamilton, Ohio, he removed to New York City, and engaged in active practice, where he had rare opportunities for observation and experience, and enjoyed the esteem and friendship of many of the most distinguished physicians and surgeons there, who will be grieved to learn that he has passed away.

"In 1872 he married, and two years later located in Lexington, the home of his ancestors, and there continued his professional labors until they were arrested by remorseless disease, and death closed his useful life.

"By that death the medical profession is deprived of an intelligent, competent, and useful member, and the community of an honorable and worthy citizen.

"And it is our desire that a copy of the foregoing be transmitted, by the Secretary of this meeting, to Dr. Dudley's family, with assurance of our heartfelt sympathy and condolence.

"Also that the papers of Lexington and medical journals of Kentucky and New York and Pennsylvania be requested to publish them; and that as a further evidence of respect, we attend his funeral in a body.

"M. T. Scott, M. D., *Secretary*,
"H. M. Skillman, M. D., *Chairman*."

JAMES PATTERSON CASSELLS,

Aural Surgeon, Glasgow, Scotland. It is with feelings of the most profound sorrow that we record the death of this most estimable physician and aural surgeon, who died at Glasgow, April 13, 1884, aged forty-eight years. With a constitution enfeebled by a railroad accident, Dr. Cassells was one of the most indefatigable workers in his department. His numerous contributions to medical journalism were known and read of all men. He was Chairman of the Section of Otology of the British Medical Association, Secretary of the Section of the International Congress which met at Amsterdam, and of the same which met at London. Dr. Cassells translated the work of Dr. Auther Hartmann, of Berlin, on Deaf-Mutism, but his crowning work was the opening of a distinct ward for the treatment of diseases of the ear in the Glasgow Hospital, and the translation and editing of the great work of Professor Adam Politzer, of the University of Vienna, of which the author states in a letter to the translator, "I have read it, and am very pleased with your translation of my work into English. Receive my thanks for the trouble and patience bestowed on it." Dr. Cassells was a member of the Royal College of Surgeons, England; Fellow of the Faculty of Physicians and Surgeons, Glasgow; Aural Surgeon to and Lecturer on Aural Surgery to the Glasgow Hospital; and one of the editors of the Archives of Otology, published in New York and Heidelberg.

QUERIES AND REPLIES.

Dr. B., of Pa., asks for reliable statistics of the relative frequency of acute pneumonia and pleurisy.

Dr. S. K., of Pa.—The proper pronunciation of the word is gyn-e-col-o-gy, the initial *g* as in *gin*. It is a piece of pedantry to introduce the hard sound of the Greek *gamma* into English words, when the analogy of our tongue is so strongly against it.

Dr. G. W. Johnson, of Illinois, writes to say that in answer to his inquiry about tæniafuges, he received various suggestions, and finally settled on the oleo-resin of Koosso as the most efficient. It is imported by various first-class drug houses.

MARRIAGE.

THORWARTH—MOORE.—At the residence of the bride's parents, May 22, 1884, by the Hon. G. W. Cooley, J. F. Thorwarth, M. D., of Smith River, Cal., and Miss Dora E. Moore, of Ellensburg, Oregon.

ORIGINAL DEPARTMENT.

LECTURE.

A LECTURE ON SOME PHASES OF CORNEAL DISEASE, ILLUSTRATED BY SIX CASES.

DELIVERED TO THE POST-GRADUATE CLASS IN THE UNIVERSITY OF PENNSYLVANIA, BY S. D. RISLEY, M. D.

Instructor in Ophthalmology, and Ophthalmic Surgeon in the University Hospital.

Reported by G. E. De Schweinitz, M. D., Assistant Physician in the Eye Department.

Gentlemen: To those of you who are somewhat familiar with eye diseases from your former studies, I need say nothing of their importance. To those whom I have the pleasure of addressing for the first time, their importance cannot be well overrated. This becomes obvious when we remember that nearly all tissues of the body are represented in the eye and its appendages, and are liable to all the pathological changes which affect like tissues elsewhere in the body. Moreover, slight changes in tissues so highly organized, lead to the most important alterations in function. Blindness is a calamity which all recognize and seek to avoid, but the minor defects of vision, while they do not excite in the same degree our compassion, are nevertheless of great importance to the individual, since they not infrequently seriously mar his future career, debarring him from those pursuits in life which demand accurate eyesight for their successful accomplishment.

From your physiological studies you know that in order to see with comfort, the eyes should act in harmony, their muscular apparatus should be in order, and their refraction perfect enough to allow parallel rays of light to be focused accurately upon corresponding points of the retina, in each eye the point of distinct vision being the *macula lutea*. If now a muscular anomaly exist, or there be an error of refraction, or if one or both of these faults be present, perfect vision is no longer possible, and discomfort ensues. You may search far and wide to find a perfect eye; for just as we see distortions of various parts of the body, deviations of the nose, structural peculiarities of the fingers, toes, and the like, so also we constantly find distortions in the shape of the eyeball, *e. g.*, elongation or shortening of its axis. Not only are eyes constantly affected with these anatomical departures, but they are subjected to like troubles accruing from disease. Among the very common diseases of the external tissues of the eye are those of the cornea, *e. g.*, minute ulcers, which result either from an existing dyscrasia, or are due to traumatism, examples of both of which conditions are present here to-day. After an ulcer is once present, it is doubtful if the tissue is afterward perfectly restored. There has been an interruption in the continuity of the epithelium, and it is doubtful, I say, if this is again perfectly renewed, so that rays of light passing through such cornaæ are more or less interrupted, and irregularities of refraction ensue. I will now briefly exhibit the series of cases which I have brought before you to-day, and speak of them more in detail later.

1. Here is a young man who, a few days ago, was switched in the eye with the tail of a horse, causing an *abrasion* of the cornea at its lower margin. It is now in the process of repair. The epithelium has been torn away, but is now renewed,

and in its place you can still see the slight infiltration due to the pressure of new cells brought thither in the process of repair.

2. This man's difficulty you can readily see, consisting of a nearly central scar on either cornea, the site of former ulceration.

3. In this woman I show you another example of ulcer of the cornea, which has also undergone the process of repair, but in a manner differing from either of the preceding cases. In place of filling up it has repaired with an actual loss of substance, leaving this little saucer-like excavation. In this case, not only was the epithelial covering carried away, but also some of the deeper corneal structures.

4. In this young woman's case you see the right cornea occupied by a bluish-white cloud, while in the left eye the conjunctiva is studded with minute blister-like elevations, technically known as *phlyctenulæ*.

5. This little child is so much better to-day that while I rejoice to see his improvement I regret that you, for the sake of instruction, did not see him when he first came to the Dispensary presenting a picture that I will later endeavor to paint in words for you.

6. In the case of this young woman you see a central ulcer, but in addition the cornea is vascular throughout.

At first sight these cases bear a remarkable resemblance the one to the other, but their pathological significance is vastly different, which fact has already been pointed in the one instance between the healing of the corneal abrasion and the ulcer which repaired with loss of substance leaving an excavation. In healthy young men there is seldom so much trouble arising from an abrasion of the cornea, (Case 1.) Some of the epithelium was scraped off by the blow from the horse's tail, and probably from neglect, irritation or the effluvia arising from the stables, more inflammation than is usual was set up in this case. It is always a painful affair. From your anatomical studies you know that the cornea is abundantly supplied with sensitive nerves. The epithelial covering now being removed, the exposed nerves are constantly subjected to irritation, setting up a painful and uncomfortable state of affairs, comparable to the mischief brought about by the presence of a foreign body in the conjunctival sac, an experience which, no doubt, all of us have endured. Usually these injuries repair quickly.

A few years ago I saw an Italian one-half of whose right cornea had been abraded by the thrust of he bough of a tree. He came originally twelve hours after the injury, and again twenty-four hours later, at which time the seat of the injury was scarcely visible, and except for a faint bluish-white cloud, only demonstrable by the aid of oblique light and a two-inch lens. The cornea was clear.

Treatment.—An eye of this kind should be bandaged preferably with a white flannel roller, like the one I exhibit here. The roller should be placed over a compress of absorbent cotton, which when applied will keep the eye immobile, and thus avoid irritation. Locally, you should use a boracic acid wash (gr. xv., f. ℥j.), but if this be not sufficient, it may be enforced by the instillation of a drop or two of a solution of sulphate of atropine (gr. iv., f. ℥j.), or if the irritation be only slight, you may use a solution of hydrobromate of homatropine (gr. iv.–vi., f. ℥j.)

Had you seen this child (Case 5) at his first visit somewhat of the following picture would have been presented to your gaze. He came into the Dispensary with his eyes spasmodically closed, his head bowed upon his arm to exclude the light, or more often deeply buried in his mother's lap, to be sure and forbid the entrance of any chance side-rays, so great was his dread of light, or, as it is technically known, photophobia. Inspection of his eyes was difficult. This is best accomplished by placing the child upon his mother's lap, taking his head between your knees —thus—and protecting the end of your finger with a small piece of old linen; press the upper lid up and back, and at the same time draw the lower lid down. Having done this in the present case, you would have seen that the conjunctiva was injected and red, but translucent. The eyes filled quickly with tears. The corneal margin was surrounded by a chain of blisters and approached by numerous dilated blood-vessels. On the centre of the cornea, where you to-day saw the white spot, was an open ulcer. If we had seen this at an earlier stage of the disease you would not have observed an open ulcer, but a blister-like body due to the raising up of the epithelium by the fluid collected beneath, at least such is the usual history of the phlyctenular ulcer. The corneal nerves become exposed; the rubbing of the lids causes excessive irritation, which in turn sets up increased secretion, and soon the blister develops into a typical corneal ulcer.

One point I must speak of right here, and that is the difference between an eye of this sort and one due to cold-taking.

In the latter case, the conjunctiva is opaque.

There is a flow of mucus and an absence of photophobia, while in the former case, there is marked lachrymation, excessive dread of light, with spasm of the orbicularis, and no opacity of the conjunctiva.

Just as the symptoms differ in these two classes of cases, so also do the causes.

Here we see a large number of the cases of phlyctenular disease, while they are not so common in private practice. We see them in a public service such as this is, because they come from the alleys and small streets, where the houses are damp and poorly ventilated, and the inmates insufficiently clothed and fed, and where, in addition to these faults in hygienic and dietetic surroundings they have often inherited some dyscrasia. Usually, in addition to the local manifestation there is derangement of the alimentary canal, loss of appetite, and investigation will show enlargement of the cervical, post-cervical, and submaxillary glands, with a strong tendency in these glands to suppurate, thus plainly indicating the taint which justifies the name *strumous ophthalmia*, so often given to this disorder by the text-books.

None of the cases before you to-day are in such pronounced indigent circumstances, but you must remember that improper food is as bad as insufficient food. Men who receive small wages and have large families, cannot afford to buy fresh meat daily. They naturally turn to the cheaper forms—salted meats, unpalatable bread, and drink largely of tea. You will be surprised when you come to investigate this matter how many men and women there are who eat meat but once a day, the morning and evening meal being largely composed of bread and tea. Hence, the children of such parents grow up with insufficient physical backing, and, indeed, are fortunate if they have not inherited in addition a strumous, phthisical or syphilitic constitution.

Treatment.—The sheet-anchors of treatment are cod-liver oil and the iodide of iron. In addition, shut out their evil surroundings as far as possible, and stop all sweetmeats, for it is astonishing that even among these people a few pennies can always be spared, with which the child is allowed to buy candies and cakes. Advise fresh meat at least once a day, and plenty of good bread and milk. See that the patient has a tepid bath daily. Look after the alimentary canal, and when the child has five or six greenish stools daily, administer suitable remedies, such as you have been taught to give from other chairs in similar conditions.

Local Treatment.—Sulphate of atropia is indicated in almost all cases, and the moment the pupil dilates the photophobia diminishes. It is often difficult to obtain this dilatation. Keep the child in your office, frequently instilling a drop of a solution of sulphate of atropia (gr. iv., f ℥j.) until the desired end is reached, and then when you send the case home give the mother a similar solution, with instructions to put one drop into the eye three or four times daily. The child should further be made to wear a pair of smoked glasses, and not be allowed to bury its head in the mother's lap or pillow. When the irritation has passed away under the use of the atropine treatment, you may dust some calomel into the eye, the calomel being best prepared by the process of sublimation. Put the head back, draw the lower lid down, and having dipped a camel's hair brush into the box or bottle containing the powder, dust a little of it into the eye—thus.

Sometimes, instead of the calomel you may use an ointment of the yellow oxide of mercury (gr. i., ʒj.), of which a small portion is placed into the eye, and then gently rubbed in. One caution I must give you here, and that is not to use, or at least use very guardedly, calomel in this way, when the patient is taking iodide of potash, or any preparation of iodine, as, for instance, the syrup of the iodide of iron. These preparations are freely eliminated by the tears, and form, with the calomel, a soluble iodide of mercury, which acts as an intense irritant to the eye. You will often be gratified to see improvement in the eye by mere local applications before your constitutional remedies have had time to take effect, but more often the local treatment is of no avail, except to diminish discomfort until the system comes under the influence of the internal medication. You should make it a rule to attack these cases early. You can see the white patch or cloud in this child's cornea, and of course light cannot penetrate any more than it could pass through ground glass, or at least no distinct image can be formed. Hence, what originally appeared a simple matter, has marred this child's vision for life. What is present in the child's case is also present in this young man's eye (case 2), and although the scar does not cover the pupillary space, still it is in the axis of vision, and will interfere with the perfect refraction of the eye.

Myopia often occurs in connection with opacities in the cornea, which is probably due to the indistinctness of the retinal images, the patient seeking to make up for what he loses in distinctness by increasing the size of the image. To obtain this he bows his head as near as possible to the

object, producing a strong strain upon the accommodation, and of course corresponding convergance of the visual axis. His history is an interesting one, for he tells me that every summer, for the last seven, he has been attacked with sore eyes, showing the existing dyscrasia which was at the bottom of the trouble; but it is only the last attack which left the central scar. The ulcer in many instances does not occur centrally, but more often, probably, is situated between the corneal pole and its limbus, and when it occupies this position perforation is more apt to occur. The dread of light increases, the ulcer burrows deeper and deeper, and finally reaches the membrane of Descemet, and this, by reason of the intra-ocular pressure, is pushed forward in a minute, cone-shaped protrusion into the the bottom of the ulcer, and this, in its turn, may also rupture. If this happens, the anterior chamber is emptied, the iris is pressed forward into the bottom of the perforation and then becomes adherent. The pupil is now distorted in shape, and with every change of light and shade the iris is dragged upon, and hence is a constant source of irritation. Besides, the changed shape of the pupil no longer permits the proper entrance of the rays of light, and perfect vision is no longer possible.

The woman (Case 3) with the saucer-like excavation in her cornea, came in time to prevent perforation, but not in time to avoid loss of substance and hence loss of the uniform curvature of the cornea, so that the mischief done in her case is also great. You have often seen a blister upon a window-pane and know that you cannot see through it distinctly. Much the same state of affairs is present in this cornea. The rays of light may pass through the cornea around this blemish, and vision may be good for large objects, but distinct and accurate vision for small objects, like fine print, is impossible.

This woman (Case 4) came to me originally two years ago with an ulcer of the right cornea. Her history is an interesting one. She worked at pasting shoes in a badly-ventilated and lighted room, and her health became impaired. Her breakfast consisted of bread and tea, which she ate with poor appetite. She took with her a cold lunch, and ate this with little or no relish. When she returned at night she was too tired to enjoy her supper, and generally retired suffering with frontal headache. In addition, she was afflicted with retroversion of the womb. This was corrected, and under improved diet and hygiene, together with the use of the syrup of the iodide of iron and proper local treatment, the ulcer was cured. At the end of a year she returned with the same trouble, and was again cured; but the diseased has recurred three or four times, the last attack leaving her with these spots on her cornea. This summer she again came to the Dispensary with an ulcer upon the cornea, and was nearly well when she was attacked with a colliquative diarrhœa, an old sinus in the axilla opened, and the disease of the eye recurred afresh.

I have related the clinical history of this case somewhat in detail, because it so markedly illustrates that the disease of the cornea is not purely a local one, but rather a local manifestation of a constitutional taint.

Communications.

NOTES OF SOME FATAL CASES OF PUERPERAL SEPTICÆMIA WHICH OCCURRED IN THE PHILADELPHIA HOSPITAL ABOUT FEBRUARY, 1883.

Reported by A. R. Johnston, M. D., of New Bloomfield, Pa.

The number referred to, their position, on the hospital record, and the length of time, includes the times from the first pain, regardless of perceptible dilatation, until the end of the third stage.

Case 110, delivered January 27, æt. 20, primipara; child presented in first position, and labor lasted six and a half hours. Weight of child, six pounds. This was a very easy labor, and the patient did not attract the attention of any one until a few minutes before delivery. The attendant resident was called, and when he arrived, the head was born with a caul. The womb felt solid and of about the ordinary size. No ergot was given at this time, about 6:30 a. m. A bandage was applied about half an hour after delivery, and the woman moved to another room, a distance, in this case, of about seventy-five feet. (The rule of the house is to confine all the patients upon the same bed, which is composed of a bedstead with a strong gum bottom, rollers upon which it moves smoothly upon the floor, and the necessary amount of bed-clothes. After they are washed, bandaged, and dressed, they are moved upon this bed, under abundant cover, to their lying-in bed.) After she was put to bed she did not complain of anything, and soon went to sleep.

At 2:30 p. m. the resident was told that she had slept most of the day, and had just wakened complaining of weakness. The bed was much stained with blood, the patient was pale, sleepy,

and listless, pulse 170, fundus felt on right side half way between the umbilicus and ribs. The vagina was distended with a coagulum, which at first felt like the placenta on account of its toughness. The blood in the uterus, probably between a pint and a quart, was more fluid. The blood and coagulum were cleared out, and a strip of membrane found in the os. Two drachms of fluid extract of ergot were given, soon followed by vomiting. The head was lowered, hot-water injections were used, and an ounce of whisky, in milk, was given in small amounts. Twenty drops of tr. digitalis was given hypodermically. The temperature after this was 101°, and the pulse rapid and intermittent. She rallied pretty well, and there was no tendency to relaxation of the uterus. The pulse at 4 p. m. was 150; at 6 it was 125, and better in volume and rhythm. The temperature at 6 was 100°.

On the morning of the 28th, there was tenderness of the abdomen, with some distension. Vomiting, with comparatively clean tongue and no nausea, was a prominent symptom. Color of vomit varied, being green, dark, and yellow. The lochia were profuse and fetid, and increased in these properties until death.

On the morning of the 30th, she complained of pain in the left leg. It was affected with phlegmasia dolens. The swelling did not increase much, and the thigh was never affected with pain or swelling. The temperature of the case was as follows:

January 27. Evening, 100°.

January 28. Morning, 100°; evening, 101°.

January 29. Morning, 99.8°; evening, 102°.

January 30. Morning, 99.8°; evening, 101.8°.

The pulse was always rapid and generally intermittent.

On the 28th, it averaged about 125, after that 140 to 150, until the last twelve hours, when it reached about 175. The respiration was hurried during the last thirty-six hours, and before death was as frequent as thirty-two per minute. There was no delirium in this case at any time.

Treatment was as follows: Whiskey, eight ounces daily; tincture of digitalis at first fifteen drops, afterwards increased until thirty were given every four hours. It was given in whiskey at first, and afterward hypodermically. Morphiæ sulphas was given in quarter and third grain doses four to six times in the twenty-four hours, hypodermically. Lead water and laudanum were applied to the phlegmasia dolens, and the pain greatly increased. After this unguents were used. Hot flaxseed meal poultices were applied to the abdomen every two hours.

Patient died January 31st, about ninety-six hours after delivery.

The bed next to this patient was occupied by a woman suffering primarily from an apparently rheumatic affection of the knee, followed by a severe sore throat, and who after this, and about synchronous with the abdominal symptoms of this patient, developed facial erysipelas. The case of erysipelas was removed January 30th, and attended by other doctors and nurses. She was delivered of a living child, probably somewhat premature, February 2d. She died a few days after delivery, but as she was not in the obstetrical ward I did not see her, and do not know what her symptoms were after delivery.

Case No. 108. Æt. 23, first pregnancy. Child presented in first position, and labor lasted forty-one hours. The child was born January 26th, and weighed seven and three-quarter pounds. The patient was a vigorous and apparently healthy woman. This was a slow and difficult labor from the beginning, and after it had been in progress about forty hours, the natural efforts ceased to have any propulsive effect whatever. The pains were almost constant, were very distressing, and the head stuck in the pelvis. Dr. E. P. Bernardy, the physician-in-chief, made his regular visit to the hospital at this time, and decided to use the forceps. They were adjusted, and as the patient complained a good deal, sufficient ether was given to relieve the pain and produce some relaxation, but profound anæsthesia was not produced. There was no laceration of the perineum, but the carunculæ myrtiformes were prominent, and were injured to a slight extent.

During the first ten days there was nothing unusual in the condition of the patient, and no record of pulse or temperature was preserved. I have placed case No. 110 before this one in these notes, because she was the first to present untoward symptoms. On the morning of January 29th the abdomen was large and tympanitic. The patient did not complain of pain, and a considerable amount of pressure did not elicit tenderness. Her tongue was covered by a white fur. Calomel in half-grain doses was given until a motion from the bowels was obtained, which required four doses. About four o'clock p. m., seventy-six hours after delivery, the resident was sent for in haste; the patient complained of great pain in the right side of chest and right shoulder, which came on suddenly. There was no tenderness, and she could not localize the seat of pain. The breathing was shallow and restrained, pulse irregular and about one hundred and sixty per minute.

After this time the breathing was always embarrassed, and the pulse between one hundred and fifty and one hundred and seventy-five. The lochia were rather offensive, but not profuse, and appreciably diminished after this time. This evening she vomited a dark muddy liquid, and the following day a grassy-green liquid. There were several alvine evacuations during the night and following morning. Transient delirium annoyed the patient, growing worse until death.

The temperature on the morning of January 29th was 103°; evening, 103°. January 30th, morning, 102°.

Treatment ten grains of quinine morning and evening, tincture of digitalis twenty drops every three hours, six ounces of whiskey daily, and hypodermics of morphia, according to indications. Poultices were applied to the abdomen and chest. Patient died on the evening of January 30th.

This woman, with three others, occupied a room, the capacity of which was about six thousand cubic feet. The room was warmed by a stove, and adjoined the one in which all the patients were confined. The patient next to her was delivered January 28th, and the other two January 18th and 24th. All were attended by the same doctor and same nurses, without any precautions other than cleanliness, and there were no symptoms of septicæmia in any of the others.

Case 115 delivered February 22d, æt. twenty-one, primipara, first position, and labor lasted thirty-six hours. Child weighed nine and three-quarter pounds. This case was sick and vomiting during the last twenty-four hours of her labor, and was much prostrated after delivery. The perineum was found to be ruptured, and was operated upon about two hours after delivery, the patient being under the influence of ether. During the day there was no complaint of pain, no nausea after delivery, the pulse was one hundred and ten to one hundred and twenty, and the tongue was covered with a yellow coat.

February 3d complained of pain in the abdomen, tongue still coated, and there was distension of the abdomen. Temperature in this case was as follows: Evening of February 2d, 98.8°. February 3d, morning, 99°; evening, 103.8°. February 4th, morning, 102.4°; evening, 105°. February 5th, morning, 100°; evening, 102°. February 6th, morning, 99°; evening, 103.2°. February 7th, morning, 101.8°; evening, 102°. February 8th, morning, 101°; evening 105.2°. February 9th, at 7 a. m., 100°, and at 10 a. m. 105°.

She took her nourishment, which consisted chiefly of milk and whiskey, without nausea or vomiting until February 5, and seemed to be improving in every way except the pulse, which kept in the neighborhood of 125, but with good volume and rhythm. At this time she began to vomit without any considerable nausea. The tongue retained the coating, which now assumed a brown tinge and remained so, becoming dryer until death. Morphia was administered hypodermically, and the vomiting abated, only occurring four or five times during the next thirty-six hours, and the patient feeling better after each time. She craved buttermilk, but could not drink it when it was procured for her. On the night following the 6th, vomiting and purging set in. Both were checked in the morning by hypodermics of morphia. One peculiar feature of this case was that she always thought she was getting along first-rate, and at her injunction on the night following the 7th, the nurse raised her up in bed, and allowed her to sit propped by pillows while she went to attend other patients. During the last twenty-four hours, the face and chest changed to purple and back to pale several times, and the temperature varied greatly, being 100° at 7 a. m. on the 9th, and 105° at 10. The stitches were removed from the perineum on the 8th, union was taking place, and the sore had a healthy appearance. The discharge was more offensive in this case than is usual in healthy women. Pulse 120 to 130 most of the time. Just before death it reached 170.

Treatment.—Tincture digitalis, increasing in dose until thirty drops were given, hypodermically, every four hours. Suppositories containing ten grains of quinine and half a grain of morphia every six hours, with generally a quarter to a third of a grain of morphia between times. Whiskey beginning at eight ounces per day, and gradually increased until twelve ounces were given. This woman had a large room, with no other patient in it. She died February 9, seven days after delivery.

Case 119, delivered February 9, æt. 27, primipara; child presented in the first position, and the labor lasted forty-three hours. Child weighed six pounds. There was thickening and induration of the left anterior part of the os uteri, and the first stage was slow and painful. She was sick and vomiting during the last day of labor, and after forty-two hours the first stage was hardly completed. The patient was so exhausted that instrumental delivery was the only means of relief. An anæsthetic was administered. The forceps were applied at the superior strait and the

woman delivered of a living child. The perineum was ruptured and sewn up while the patient was still under the influence of the anæsthetic. An hour later the woman seemed to be doing well, except that the pulse-rate was 130, and on examination, the physical signs of mitral regurgitation were found. During the night, she complained of pain in the abdomen.

On the following day she became delirious, so much so that toward evening it became difficult to keep her in bed. At the same time, the pulse-rate increased, became small in volume, and intermittent.

On the morning after delivery, the temperature was 99°, and on the following evening, 101°. On account of the delirium, a thorough examination was impracticable. The treatment was whiskey and digitalis with morphia, according to the indications.

Case 116, delivered February 3, æt. 23, primipara, had presented in the first position, and the labor lasted probably an hour and a half or two hours. The weight of the child was seven pounds. This woman came to the hospital on foot while in labor, and was delivered within ten minutes of the time she arrived at the confinement room. There was nothing unusual in her condition until February 8, when she complained of pain and tenderness in the abdomen. On the 10th vomiting was a prominent symptom; the pulse rate was about 125, and the temperature sometimes one or two degrees above normal. After this, the pain and vomiting abated, but the pulse and temperature remained the same, and there was no apparent gain in strength or improvement in appetite. On the 19th an eruption looking very much like measles appeared upon the chest, and spread to her face during the following twenty-four hours. It was accompanied by diarrhœa. On account of burning and itching, cosmoline was applied, and it disappeared on the 21st. It again returned and receded, appearing a third time March 2, accompanied by delirium, vomiting, and a temperature of 103° to 104°. Your reporter's term of service in the lying-in ward expired March 1, and the particulars of the case from that time cannot be given.

About this time an investigation was instituted to discover the cause of the malady. As a consequence, the resident who had been on duty in these wards was suspended for two months, but was reinstated at the next weekly meeting of the same committee. This therapeutic measure of course did not affect the progress of the malady very much, but it showed the folly of a resident having too much of one kind of sickness, and suggested the more prudent course of rendering diverse diagnoses, and thus distributing the cases to different parts of the hospital. This case was transferred. Not long afterward, so the hospital record says, Case No. 116 died of malignant scarlatina. And the epidemic was arrested and the patients saved. If you don't believe it, look at the reports of the house. Of course other deaths from "chronic Bright's disease," "pulmonary congestion," etc., followed; but what have such things to do with obstetrics? The post-mortem appearances of those examined were strikingly similar to those of the patients that had died from the influences of the epidemic, but in the present condition of science such things will sometimes occur.

These hints will be invaluable to the unsophisticated (in the absence of political or social influence), as they bear upon a plan of treatment which does not receive attention by many of our prominent authors.

Between January 18 and March 1, twenty-one women were confined in the obstetrical wards of the hospital, of whom five died. About half the whole number were affected. Almost the whole number of patients were unmarried women who came to the house, sometimes months before term, and were all assigned to the same ward. At this time there were about thirty waiting their time in a room which afforded five or six hundred cubic feet of space per individual.

When the epidemic began, isolation of those affected was not attempted, and it was noticeable that as a rule those most directly associated with the affected ones were most fortunate. After March 1, rigid isolation was instituted, and carbolized spray, carbolized cosmoline, etc., were used in profusion, with little or no effect upon the death-rate for the succeeding six weeks.

Hospital Reports.

MEDICO-CHIRURGICAL HOSPITAL OF PHILADELPHIA.

CLINIC OF PROF. WILLIAM F. WAUGH, M. D.

Reported by Frederick Loos, M. D.

Hæmoptysis—Remarkable Fecundity.

This woman comes to our clinic because she has been spitting blood. To the laity this symptom indicates the presence of tubercular consumption, and the time has not long passed when the profession, following the views of Laennec, held the same opinion. I have told you in my didactic

lectures that hæmoptysis usually indicates a morbid condition of the walls of the blood-vessels in the bronchial mucous membrane. Such a condition exists in tubercular phthisis, together with chronic congestion and relaxation of the tissues, causing an afflux of blood, and a diminution of resisting power in the vessels. For these reasons hæmoptysis is a common symptom in tubercular consumption.

But the same weakness of the vascular walls may proceed from other causes; and I shall show you that this is the case at present. This woman tells me she is 27 years old. She was born in Philadelphia, of Scottish parents. Her mother had eight children, including one double birth. Her husband is also a native of this city, his parents being Germans. His mother had eight children, all single births. He is rather below the medium height, of medium physique, temperate and healthy, and is a morocco-dresser.

Our patient is somewhat above the usual height of women, fair, handsome, well-built, with broad, capacious pelvis. She is rather pale just now, and you can see the blue veins on her face more plainly than I would wish; but her lips are red, and the circulation good. Her pulse is somewhat compressible, and the veins on her hands rather full.

This couple have been married nine years; and although there is nothing in the above description in any way unusual, they have achieved the most remarkable success in obeying the injunction to increase and multiply, which has ever come under my observation.

The first child, a boy, was born October 30, 1872, and is now alive and well. In July, 1875, she had twins: a boy still-born, and a girl who lived two years, and died of marasmus. On September 4, 1878, she had triplets, a boy who died in seven weeks, and two girls, still living and well, though small for their age. In February, 1880, seventeen months later, she had twin girls, one of whom died in three months of marasmus, and the other a month later of cholera infantum. On May 22, 1881, fifteen months later, she had twins again, a boy and a girl, who lived five months, and died of whooping-cough.

You will thus see that she has borne *seven living children in the space of thirty-two months!*

I would recommend this case to the consideration of the alarmists who croak about the degeneracy of the European race in America. I have been unable to find an instance of equal fecundity on record. I am firmly convinced that if American wives are not surrounded by large families, it is because they do not desire them. A woman once told me she had produced abortion in her own person no less than seventeen times!

Let me take this opportunity to adjure you, as physicians, to set your faces resolutely against the practice of preventing conception. From disinclination to bearing the discomfort of pregnancy, and the deprivation of society, and from a selfish desire to save the expense of bringing up a large family, our American women are growing yearly more unwilling to bear children. It is incredible with what utter disregard of moral considerations women look upon this matter. Ladies in the highest walks of life, apparently endowed with every Christian grace, whose walk and conversation are faultless in every other respect, look upon the person who can teach them how to avoid conception as a benefactor to the sex.

When wives voluntarily degrade themselves to the position of the mistress, when they defile the marriage bed with the appliances of the brothel, what wonder is it that they find the honor of their husbands weakened, and the loyalty due to them lost in selfish indulgence not more criminal than their own?

But to return to our patient. What has been the result of this great activity of the reproductive function? To the children it has been disastrous. Nursing two children while others were developing in the womb, the supply of nutritive material she could supply has been defective in amount and in quality, and all have suffered. One child was still-born, and six others succumbed to marasmus, or diseases incident to childhood which they had not strength to resist. The two of the triplets still living are small and puny. Hence we may say that such frequent births lead to the production of a deteriorated race, incapable of supporting the vital functions under ordinary circumstances. In general terms, we may say that if births are less than two years apart, the result is apt to be a deteriorated product.

To the mother, what is the result? You see it before you. She is weak and pale, and has been spitting blood for a year. When the children nurse she has pains in her chest, and if the nursing be prolonged she faints. Every movement of her body indicates languor.

On examining her chest, we find no evidences of tubercular disease; physical examination giving negative results. A blowing murmur at the base of her heart indicates anæmia.

Now, in searching for the causes of the morbid condition of her bronchial capillaries, which evidently causes the hæmoptysis, just think what enormous amounts of nutritious materials have been drawn from this woman's system to build up the frames of so many infants! The organs of her body could not assimilate so much from her food; and the balance has been drawn from her body until every tissue is drained. While the loss has been of *all* the elements of nutrition, the one which has been principally felt in this case is lime. To the loss of this element, we attribute the general weakness, and particularly that of the bronchial capillary walls. To confirm this view, just look at her teeth. Three years ago, she had a perfect set of teeth, and now you see they are riddled with carious cavities. Ask any mother when her teeth began to decay, and she will tell you during pregnancy. She then parts with the phosphate of lime in her teeth to build up the tissues of her infant. Hence comes the strange longing of pregnant women for chalk, slate pencils, etc., a longing which a thoughtful physician should take warning by, and prescribe a plentiful supply of this element.

Now, what is our prognosis in this case? She will recover if she obeys our directions carefully; and as she is of more than ordinary intelligence, I believe she will.

She must, if possible, avoid becoming pregnant for two years. For this purpose, we recommend simply moderation and a self-restraint on the part of her husband. We may do this much

with propriety, but beyond this we dare not go, even in so aggravated a case as the present. She must have a plentiful supply of nourishing food, taking pepsine and muriatic acid with each meal, to add to her digestive capacity. She must have the open air, preferably at the sea-shore, moderate exercise, warm clothing, and every morning a cold shower-bath of the shortest duration, to be followed by vigorous rubbing with a coarse towel, and a cup of hot beef-tea, to be drank immediately after the bath. No remedy has the beneficial action upon the blood of anæmics that the shower-bath has when properly used. We advise her to avoid water and slops or soups, which unduly dilute the blood.

We order for her an emulsion of cod-liver oil, with lacto-phosphate of lime. It is in just such cases that this combination is so markedly beneficial that it has obtained an undeserved reputation as a cure for tubercular consumption.

A prophylactic it assuredly is, as the case before us might, under certain circumstances, develop into a true phthisis. Let us hope that the bacillus tuberculosis may not chance upon this very promising soil until she has taken the prescription for some months, when we will no longer fear it.

The patient whose case is related above returned to the clinic at the end of six months. She had entirely regained her health; the hæmoptysis had long since ceased, and every evidence of ill health had disappeared. She became pregnant one year later, was carefully attended by her physician during pregnancy, and had no return of hæmoptysis. The emulsion was given during her pregnancy continuously, and throughout lactation. The infant was finer and heartier than any of its predecessors excepting the first.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, May 23, 1884. Dr. Henry Beates, Jr., in the chair.

Dr. Mary Willets reported a puerperal case with numerous complications. Mrs. H——, æt. 30, primipara, after a normal delivery, did well for twelve days. Then, after pain in her back and limbs, and chilly sensations, had a rise of temperature and was attacked with nausea and vomiting. The temperature continued high for two weeks. There was nothing to account for the supra-normal temperature, except a laceration of the cervix uteri and some tenderness around this point. On the twenty-fifth day after delivery the patient complained of pain in her left leg. For more than a week there was pain and swelling both above and below the knee; the pain greatly increased on pressure and attempts at extension of the limb, and was in the course of the femoral vein, but careful examination failed to discover anything abnormal. On the forty-third day, the patient having recovered sufficiently to go down stairs, we were suddenly confronted with well-developed mania, at first violent, but subsequently becoming merely loquacious. This continuing two days, gave place to somnolence, and five days later, to convalescence.

Dr. E. E. Montgomery remarked that the case was unusual from the lateness at which the fever appeared. During his present term at the Philadelphia Hospital, measures had been instituted to prevent the contact of septic matter with the parturient parts. A solution of corrosive sublimate, one to two thousand parts, was used to sponge the parts after placental delivery; and cloths saturated with the solution were kept in place by absorbent cotton, oil silk, and a tail bandage. There had been but three cases of septicæmia during the present quarter.

Dr. A. H. Smith said the local examination which the reader of the paper had very properly made solved the whole problem. Together with the symptoms, it showed the case to be one of pyæmic—not septicæmic—poisoning in a woman feeble and unable to resist the absorption of pus. Septicæmia cannot arise after all open surfaces have become purulent. The examination was valuable, and he thought it would be better if more care was generally exercised in this direction.

Dr. Philip M. Schiedt read a paper on the

Clinical Phenomena Following the Puerperal State in Two Cases.

In the first case he was suddenly summoned to the bedside of a woman aged about thirty-five, whom he found comatose, with undilated pupils, head drawn to left side and flexed on the chest, a clammy sweat on forehead, and imperceptible pulse. The heart-sounds were faintly detected, and the body and extremities warm. Restoratives and artificial respiration were without avail, and the patient soon expired.

The history of the case, subsequently ascertained from the family physician, was as follows: She had been delivered of a child, after a natural labor, two weeks previously, which was followed by a normal convalescence, unaccompanied by fever or offensiveness of the lochial discharge. Her babe was healthy, was regularly nursed by her, and she was doing so well that her physician had ceased his visits. On the morning of her death she felt unusually well, but about nine o'clock complained of some headache; vomited a little mucus; had a heavy chill; became unconscious; and was found by me in the condition described, which soon terminated in death.

The notes were presented to the Society for the purpose of obtaining the opinions of its members as to the cause of death, the writer expressing a belief in its cardiac origin.

The other case was one of temporary blindness following labor. After a perfectly natural labor, three hours in duration, the mother failed to see her child when presented by the nurse. It was found that she was perfectly blind, and unresponsive to the candle test. She remained fully conscious and in possession of other senses. This continued three days, and was followed by gradual and complete recovery. During this time there was nothing otherwise abnormal in her condition. There was no œdema, therefore no examination of the urine was made. Previous to confinement she had been well able to attend to her duties.

Dr. L. Brewer Hall, in discussing the second case, said the most plausible explanation of such

rapidly-disappearing blindness was œdema, giving rise to choked disc. The cases reported have not been properly examined by an ophthalmologist, an omission frequently inexcusable. Some cases do not get well, and then we find an atrophy of the optic nerve. He had seen quite a large number of hysterical cases, at times monocular, and such cases are easily diagnosed by feints and attempts to discover that they do see while off their guard. Some one should always be called in in these cases to make an ophthalmoscopic examination.

Dr. Albert H. Smith acknowledged the want of exact information, while the uræmic origin of such cases had been assumed.

Dr. G. Betton Massey denied the necessity of assuming that cases of hysterical blindness were mere malingerers. Such patients at times may be perfectly honest in their inability to see; the real condition being one of divorce between the volitional and intellectual powers of the mind.

Dr. E. E. Montgomery read a paper on

Tracheotomy in Croup and Diphtheria,

based on an experience of twelve cases, one of which, a case of diphtheria, had recovered and was exhibited to the Society. Five of the operations were for diphtheria, the remainder for croup. In all, the operation was one of last resort, and the series teach the importance of early operation. Death occurred most frequently between the third and fouth days: one died in fifteen hours; a second in thirty-six hours; and another on the ninth day. In the successful case the canula, owing to laryngeal spasm, remained until the twenty-fourth day.

In operating, he gives chloroform, and avoids hemorrhage by transfixing a fold of the skin, held by himself and assistant, making an incision one inch long, completing the dissection to the trachea by the forceps and grooved director. After opening the trachea care is observed to remove all membrane previous to insertion of canula. After treatment consists in attention to tube, keeping several thicknesses of tarletan wet with hot carbolized water over it. The temperature of the room is maintained at between 75° and 80° F., and stimulants and good food given, together with quinia, tincture ferri chlorid. and corrosive sublimate—the latter in frequently repeated doses. The attempt is made to dispense with the tube from the fifth to the eighth day, but it should not be removed until respiration *per vias naturalis* is fully established. From these cases he draws the following conclusions:

1. That tracheotomy is justifiable in diphtheria as well as croup.

2. That it should be performed in croup when it is evident that drugs do not control the progress of the disease, particularly when there is depression of the lower end of the sternum during inspiration; in diphtheria, with the advent of suffocating symptoms.

3. That in the performance of the operation, the knife should only be used to incise the skin and trachea, the intervening tissue being torn by director and forceps.

4. That the subsequent use of proper drugs will promote a favorable result.

Dr. Collins recalled several flattering cases which in a few days showed crape on the door. He doubted the propriety of anæsthesia, but thought the operation justifiable, if only as a means of easing death.

Dr. Wm. H. Parish said this operation, which was one of the easiest in performance, should be resorted to whenever the symptoms were of such a character as to show impending suffocation. To determine this requires no little judgment, and he recalled a case of recovery without operation, where both himself and Dr. Allis agreed it should be performed. He treats diphtheria by large doses of chlorate of potassium and iron.

Dr. W. H. Warder, in discussing the treatment of diphtheria, thought the chloride of potash and tr. ferri chlorid. most successful in ordinary cases. In more malignant ones he had resorted to calomel in five-grain doses. In a case which Dr. Pepper had seen with him, the latter advised a continuance of this plan for forty-eight hours. At the end of this time forty grains had been taken; a large and offensive evacuation followed, and the child recovered. He did not think such large doses usually necessary, however. Much of the calomel passed without other change than oxidation.

June 27, 1884. The President, Dr. Henry Beates, Jr., in the chair.

Dr. G. Betton Massey read a paper on

Traumatic Sciatica and Its Relation to Hip Injuries.

Details of six cases were related, in the majority of which the sciatica had been overlooked, while attention was directed to a search for osseous injury. In the first case he was called in consultation to see an aged gentleman who had fallen on an icy spot of pavement eleven days previously. In falling, he struck heavily on the left hip, and it was with difficulty that he arose and walked home—a distance of four and a half blocks. His family doctor, a prominent physician and an expert diagnostician, when called in searched diligently for fracture, but could find none—notwithstanding the evident helplessness of the limb and the attacks of excruciating pain, that was made worse by movement. At the time he was called in, the physician had about concluded that the pain must be imaginary.

On examination, the absence of any kind of fracture was apparent. The patient could lift the limb but a few inches from the bed. He was suffering from continuous and severe pain, felt most at points corresponding to the sacro-iliac notch of the affected side, the rear of the head of the fibula, and the rear of the external malleolus. The pain was aggravated by any movement, but especially by flexion of the thigh and extension of the leg. It was clearly a case of sciatica caused by contusion of the nerve in falling.

At the request of the medical attendant, the reader of the paper joined him in the care of the case and applied the continuous descending galvanic current to the affected nerve, ending each sitting with a series of muscle-contracting interruptions of the current; great gentleness being required at first to avoid aggravating the pain temporarily. Good effect was manifest after the first visit, and eleven applications sufficed to establish a complete cure—recent careful inspection failing to detect either awkwardness of gait or atrophy of the posterior muscles.

Case 2 was that of a German woman aged 73. On the 15th of January, 1883, she fell on the ice, fracturing the neck of the femur, outside the capsular ligament. After being totally neglected for two weeks, a member of the family asked the reader of the paper to take charge of the case. He found the limb one and a quarter inches shorter than its fellow, and greatly everted. At the seat of injury the great trochanter was lost in an abundant deposit of callus. No crepitus could be found. Great pain existed throughout the distribution of the large sciatic nerve, being especially felt in the peroneal and posterior tibial branches. Considering the age of the patient and the attempt at union already made by unaided nature, it was deemed unwise to interfere with the broken bone, so remedial efforts were entirely directed towards the relief of the sciatica. A series of blisters were directed; chloroform injections made; various stimulating and anodyne liniments applied, together with the internal administration of opiates and sedatives; but he felt bound to say the case seemed slowly to improve without being affected by any of these remedies. Electricity was not used, as the patient was too far from the office to make it possible to apply it with sufficient frequency, and the friends declined to have her removed to a hospital. The pain continued over a year in gradually-decreasing severity; and though the patient has now been able to walk with crutches for some months, there is much atrophy of the muscles supplied by this nerve.

The remaining four cases were selected from the large number of cases of sciatica treated by the writer at the electric clinics of the Orthopædic Hospital and Infirmary for Nervous Diseases.

Case 3. A healthy hod-carrier was sent from Dr. Wharton Sinkler's clinic, November 16, 1881. Seven weeks before, while carrying his usual burden up a ladder, the right foot slipped on a stick and threw the thigh into extreme flexion. He immediately felt an acute pain at the point of emergence of the sciatic, and following that nerve down the thigh into the perineal. It was sharp and pricking in character, and had remained continuously present since the accident, being worse at night. He was unable to walk more than a block at a time, and presented a gait markedly characteristic of sciatica. No atrophy was found. He was placed upon static electricity, positive sparks being drawn from the painful points and course of the nerve. After the fifth application it is noted that he was much better; after the twelfth, that he walks three miles to the hospital, and after the twenty-second application he was discharged cured.

Case 4. A carpenter, aged 68, was sent from Dr. Sinkler's clinic September 29, 1880. A healthy man eight months before admission, he fell on the ice, striking the right hip. He was compelled to remain in bed six weeks, suffering from pain in the region of the small and great sciatics. His physician was uncertain whether fracture was present or not. On examination, the gluteal and flexor muscles of right leg were found much atrophied. He complained of great pain in the course of right sciatic to knee, and also in the distribution of the external peroneal. At times felt some pain in left leg. He was placed on the constant galvanic current thrice weekly. At the end of forty-two applications he is noted as entirely well.

Case 5. A man, aged 40, was sent from Dr. S. Weir Mitchell's clinic, May 6, 1881. Four months before he had fallen and dislocated his right hip. This was reduced shortly afterwards, and he remained in hospital eleven weeks, during which time, and up to his appearance at the clinic, he suffered from much pain throughout the sciatic distribution of that side. There was considerable atrophy of the buttock and limb—a difference of one and a quarter inches being found six inches below the trochanters. He was placed upon five-grain doses of potass. iodid. and the constant current thrice weekly. After thirty-five applications of the battery and considerable quantities of the iodide, it was found that the pain had ceased, but that some atrophy remained.

Case 6. A porter, aged 39, was sent from Dr. Mitchell's clinic, June 30, 1881. Fifteen months before, he had been crushed between a platform and a moving car, fracturing the pelvis on the right side. At his first appearance at the clinic some crepitus was still present, and there was two inches shortening of the right leg. He complained of much pain in the region of the sciatic nerve of the right side, which was increased by motion and exercise. He had been blistered, and was taking 5-grain doses of the iodide, when sent to the electrical clinic. After twelve applications of galvanism, with some benefit, the summer vacation compelled a discontinuance, and he did not reappear in the autumn.

The obvious conclusions to be drawn from these cases were stated as follows:

1. Surgeons called to cases of hip contusion or suspected fracture should not fail to search for evidences of injury to the delicate nervous structures here situated.

2. If such evidences of nerve injury are found, prompt and energetic measures of relief are indicated, the importance of which is emphasized by the complete and rapid recovery of the two cases which were treated early.

3. Of the four remaining cases, one was distinctly benefited and two cured by more or less long-continued (one to five months) galvanic treatment. The fourth did not receive galvanic treatment, and was fully a year in duration.

Dr. E. E. Montgomery inquired how many cells had been used in the treatment. He thought that, considering the usual obstinacy of the class to which the cases related belonged, due to the inflammation of the sheath of the nerve, the treatment had been satisfactory.

Dr. L. Brewer Hall related the details of a case similar to those described, which had been caused in a lady by a fall from horseback, alighting on the seat. The pelvis was fractured, and a long-continued sciatica supervened.

Dr. Massey, in closing the discussion, said that the number of cells used varied from twenty or thirty to fifty, the kind being the gravity cell, which, owing to great internal resistance and the nature of the elements used, did not furnish as much current per cell as the zinc and carbon batteries charged with acid. The number used was largely regulated by the varying resistance of the skins of different individuals, some

skins permitting a free flow of the current, while others presented an almost insurmountable obstacle. It is to be regretted that the inventors have not as yet presented us with an instrument that will conveniently inform the operator of the true amount of electricity passing at a given moment. An approximation, however, to accurate dosage, may be made by including a galvanometer in the circuit, or even by observing the sensations of the patient. Since the date of these cases he had used the static form of electricity in many cases of ordinary sciatica, and found it at times equally efficacious as galvanism, as well as more convenient.

Dr. Du Bois called attention to the value of *Bals. Peru.* as an application for *fissured nipples.* It should be applied after nursing about four times daily.

Dr. Hall, on behalf of the committee on microscopy, presented an improved clinical microscope, which combined all the features of a clinical with those of an ordinary table stand.

Some Observations on the Ætiology of Diphtheria.

Dr. H. Franklin Parsons thus writes in the *London Med. Times,* June 14, 1884:

Diphtheria, though the name is modern, has been known from early times. Until the middle of the present century it had, however, for nearly 100 years, been met with in this country only in the form of sporadic cases and limited outbreaks. Appearing in several parts of the country in 1855, the disease rapidly increased until, in 1859, it caused a mortality of 53 per 100,000. The death-rate then declined, with the exception of a second lesser rise in 1863, to 12 per 100,000 in 1867, about which figure it has kept constant ever since, latterly showing a tendency to rise.

A diagram was exhibited in which the curve of the death-rate from diphtheria during the past 30 years was shown, and compared with those from scarlet fever and "fever," both of which, after large fluctuations in the first half of the period, had steadily declined in the second half, doubtless owing to the operation of the Public Health Acts, and the growth of public opinion as to the importance of preventive precautions.

The Registrar-General's remarks were quoted as to the probably large number of deaths from diphtheria which are returned under the headings of "croup" and "quinsy." The mortality from diphtheria, like that from scarlet fever, is greatest in the fourth quarter of the year, and between the ages of one and five; but, unlike scarlet fever, it is more fatal to females than to males, and in rural districts than in towns. These points were illustrated by tables. Of the modes in which diphtheria may be supposed to originate, infection from a previous case is, perhaps, the only one which is certainly established. Examples taken from the author's experience were adduced.

The susceptibility of the disease varies greatly among different people, often being great in particular families. The disease is infectious in an early stage, before its characters are pronounced, and also after apparent recovery. The infection also attaches itself with persistence to houses, and may be conveyed by persons living in an infected air, who have not themselves suffered from the disease. The attendance of children at school is a frequent means by which the disease is spread, and there is reason to believe that it may be propagated from cases of sore throat of a mild character, such as frequently are prevalent at the time of diphtheria outbreaks, but which do not themselves present the typical features of the disease.

The infectious nature of the disease is also shown by the good effects which have followed well-considered and carefully executed measures of isolation and disinfection. Cases were quoted showing the length of the incubation period to be from two to five days. The hypotheses of the conveyance of the infection by the wind and by milk were touched upon.

Granting the infectious nature of diphtheria, and the difficulties in the way of tracking it, arising from latent causes, etc., it must still be admitted that it is frequent—more so than with small-pox or scarlet fever—to meet with outbreaks which cannot be traced to an antecedent case; and hence it is probable that the disease may arise *de novo.*

Diphtheria and scarlet fever are often associated, and the one disease has often appeared to have been contracted from the other.

Instances from the author's experience were given, and the nature of the connection between the two diseases was discussed.

The one disease is not protective against the other, nor is one attack of diphtheria protective against another. Diphtheria, moreover, may arise as an intercurrent affection in the course of other diseases, as measles, enteric fever, and erysipelas.

It would seem, therefore, that diphtheria should be classed in an intermediate position between the specific zymotics and the common inflammatory diseases; like erysipelas and puerperal fever, which may arise otherwise than from specific infection, but which propagate themselves readily by infection under appropriate conditions.

It is known that diphtheria can be imparted to the lower animals; but are there not diseases of the lower animals differing in appearance from

diphtheria, which may be capable of giving rise to that disease in the human subject? This question, still unsolved, is of especial importance in reference to milk; a number of outbreaks of diphtheria having been observed to follow the distribution of a particular supply of milk, though no opportunity for contamination with specific infection could be traced.

"Garget," suggested by Mr. Power, in reference on the Kilburn epidemic, in 1878, and "foot and mouth disease," were referred to.

Many authorities consider diphtheria to occur most frequently on a wet retentive soil; others that it occurs indifferently on soils of various nature. Some consider it to prefer low, damp situations; others, high, bleak, exposed sites. The author had not been able to attribute influence to any particular soil or situation, having met with the disease on clay, sand, limestone, on high chalk downs, and in the fens.

Can diphtheria be caused or propagated by unsanitary conditions? Judging from statistics it cannot, for the death-rate from the disease is higher in healthy rural districts than in the most unhealthy towns; nor has it fallen, like that of fever, in consequence of the sanitary amelioration of recent years.

On the other hand, in practice it is often found that unsanitary conditions are present in houses in which diphtheria has broken out, and the author had an impression that unsanitary conditions, such as the inhalation of drain air and fœtid effluvia, overcrowding and dampness, were not without influence upon the occurrence and course of the disease.

The cause of the disease had at different times been sought for in various low vegetable organisms, as fungi—especially the oidium albicans. More recently Oertel and other German observers had found a micrococcus abundantly developed in the affected mucous membrane.

It seemed probable that the immediate cause of the disease would ultimately be found to be some low organism, which, while capable of passing its existence outside the human body, and perhaps habitually doing so, could nevertheless, under certain circumstances, take on a parasitic habit, and acquire toxic properties.

Ruptured Urethra.

Dr. M. J. Gardiner reports this interesting case in the *Edinburgh Med. Jour.*, May, 1884:

William C., aged 19, engine-cleaner, was admitted to Ward XII., 10th January, complaining of pain about the abdomen. His friends stated that he had been squeezed that morning between an engine and wagon, and pointed to the pelvis as the part injured. On examination, patient was seen to be in a state of collapse, cold sweat upon the brow, breathing rapid and entirely thoracic. Locally, blood was issuing from the penis, and he was stated to have passed no water since the accident. Fractured pelvis and ruptured urethra were diagnosed. There was no swelling of scrotum or surrounding tissues. An attempt was made forthwith to pass a catheter. For some distance it passed all right, but just at the triangular ligament the joint was felt on a sudden to leave the middle line and pass into what seemed a cavity filled with some soft solid. Immediately blood, fluid and clotted, to the extent of about 2 oz., poured out. The catheter, however, did not enter the bladder, and further manipulation producing no better results, it was withdrawn. The urethra, then, was clearly ruptured, but whether the bladder was hurt or not was still undecided. Aspiration supra-pubically was next attempted, but owing to some defect in the mechanism, failed. A second attempt was then made to pass a catheter, and this time the very first trial succeeded. About 20 oz. of *clear* urine were drawn off. The catheter, a No. 12, was tied in, and the patient made comfortable in bed, hot fomentations being applied to the abdomen. At night the temperature was 100° F., and the patient slept well after taking 30 m. liq. morph. It was noticed, however, that the respirations were very rapid, and, on examination of the chest, the heart was found displaced to the right, and the right lung diagnosed to be consolidated throughout, with breaking down at the apex. What had been an anxious case before was now deemed to be almost hopeless. The catheter was left in for four days and then withdrawn, the urine being clear and free from blood all that time. After withdrawal the urine was at times clear, at times mixed with blood. Occasionally the urethra became blocked, but the introduction of a silver instrument always remedied matters, displacing the occluding cause, which was generally a clot of blood.

For some days patient rallied, but a temperature constantly above 100°, with profuse night-sweats and cough, gave no great hope of recovery. On the 24th a swelling was noticed in the left iliac region. This was aspirated, and a quantity of decomposing blood drawn off. Pus also now began to pass in the urine, and on the 30th patient died.

Post-mortem examination of the parts concerned showed—

Thorax.—Heart flabby and drawn to the right. Left lung healthy; right collapsed, consolidated. Bronchi full of muco-purulent material; the tissue at the apex breaking down.

Abdomen.—Omentum black and disorganized. Peritoneum black, but no active peritonitis. Cavity full of pus. Urethra ruptured; the neck of the bladder and parts around in a state of acute inflammation and sloughing. A special dissection was made of the urethra, and disclosed the penile portion and tissues around practically normal, with the exception that on the under surface, about $2\frac{1}{4}$ inches from the meatus urinarius, there was a longitudinal opening in the urethra, the length of which (by tape measurement) was five-eighths of an inch. Behind this the corpus spongiosum could be traced backwards to the posterior portion of the bulb. Here the urethra had been completely torn across, and at the seat of rupture there had evidently been a large cavity in the cellular tissue, the walls of which were in a sloughing condition. This sloughing action affected also the membranous and prostatic urethra, extending to the rectum and up into the pelvis. The mucous membrane of the bladder was normal.

Treatment of Fractures of the Skull.

Dr. J. T. Stewart thus writes in the *Peoria Med. Mo.*, May, 1884:

The importance of this subject cannot be readily over-estimated. No other fractures bear any comparison unless it may be those of the spine. The far-reaching consequences, the dreadful effects which are liable to result, even after years of comparative health, throw a fearful responsibilty on the surgeon. If it were only a matter of life and death, it would not be so bad. An error of judgment leading to an error in practice, may, and is, very apt to entail a life of misery—epilepsy, insanity, idiocy, any of which is more to be dreaded than death.

The treatment of these fractures was pretty well established by the older surgeons, and there was a fair degree of unanimity in the profession; but of late a portion of our surgeons have drifted away from the sound teachings of the fathers in surgery. These teachings were established, were the results of much observation and long experience of the finest surgeons the world ever produced.

The improvements in this case are like many of our modern improvements, in the wrong direction.

These fractures may be any form or size. They may be simple, compound, or comminuted. In any of them, in case there is no depression of bone, immediate operative measures are uncalled for and wrong; but if symptoms of compression of the brain come on and are at all persistent, then trephining becomes necessary, for that is pretty sure evidence of depression of the inner table, or at least of effusion on the dura mäter, which would be relieved by the operation.

In all cases where there is any considerable depression, whether it be a simple or compound fracture, whether there are any symptoms of compression of the brain or not, the only true practice is to elevate the depressed bone. It was to call attention to this most important thing, and obtain the views of the members, that I brought this subject to your notice to-night. There are many points of interest which we might discuss with profit for hours, but this is the great overshadowing practical question. When we are called to attend a fractured skull, shall we trephine or not? It is interesting and important to study the various kinds of fractures, the relative danger in the different regions, etc.; but compared with the vital question in a certain case, shall we elevate the depressed bone or trust the case to nature, as some advise? they are of little importance. I admit I was led to believe the conservative plan was best in almost all cases, and practiced it; but gentlemen, I have seen enough of the results of this practice to convince me it was a fatal error. I have yet to see the first man who had any considerable depression which was not corrected at the time, who, ten years after, did not suffer serious trouble from it; and some of them have become such wrecks it would have been a mercy to them and their friends if they had died when first injured. I know the line of duty is not always clear. There are cases which will perplex the wisest and most experienced surgeons. I would rather err on the side of trephining when it is not necessary than to fail to trephine in any case in which time afterwards revealed the fact that it ought to have been done. You may say, in these cases, trephine then. After a few months or years have have passed the bones become solid, and it is rare that the operation will then do any good. If there should be a spicula of bone growing down into the brain, and you can strike it and remove it, the operation would be a success; but they are the exceptional cases where this can be done.

The operation itself, if properly done, is not a very dangerous one, and then again there are many cases where Hay's saw can be used so as to make an opening large enough to admit an elevator.

The dangers of this operation have been exaggerated, and the value of it has been underrated.

Extraordinary and Probably Unique Case of Stone in the Bladder.

Dr. Alex. Patterson reports this case in the *Glasgow Med. Jour.*, June, 1884:

J. B., a retired draper, was born in the year 1828, and in his youth was a factory operative. In 1845, when at the age of 17, he fell down the well of a hoist, alighting with his legs astride an iron bar, sustaining a double fracture of the left leg, also rupture of urethra and laceration of the perineum. Through the opening in the perineum, as well as by the urethra, blood passed for a period of two weeks. Two attempts at closure of the perineal fistula were ineffectually made, and the urine continued to dribble without ceasing, compelling B. to resort to padding his clothing for the purpose of absorbing the constantly escaping urine. Several medical men saw him, but as patient was much averse to any operative procedure, nothing was attempted, although patient was aware from the year 1852 of the presence of a calculus.

On the 14th of June, 1872, Dr. G. W. was called to see patient, who was then complaining of pain in the bladder, for the relief of which sedatives were prescribed. On the 25th of the same month he was seen again, when nothing abnormal was noticeable beyond the sinus in the perineum.

On the 9th of the following month (July), Dr. W. was sent for again, when the sinus was seen to be considerably enlarged, and the patient requested the doctor to introduce his finger through the fistula, and he would feel the stone. On passing his finger through the opening, the doctor at once felt the calculus, but his finger entered a large irregular cavity in the stone, and the patient explained the presence of this by saying that he had introduced a chisel, with which he attempted to break up the mass, and had managed in this way to remove about *one ounce*.

The doctor started home for forceps, with which to remove the stone, but during his absence, whilst B. was walking about his room in great pain, the stone suddenly burst the perineum, and fell heavily on the floor, breaking into two pieces. When expelled it weighed nearly fourteen ounces and a half, which, taken with the portion removed by the chisel, makes fifteen ounces and a half, which is, so far as I can discover, about the heaviest stone on record in the annals of surgery

in which the patient recovered after its removal. The stone measured in the long circumference 10⅝ inches, and in the short circumference 8½ inches.

The lacerated perineum was dressed with carbolic oil, and on the 15th of July, six days from the date of expulsion of the stone, B. was going about collecting his rents, and performing his other duties. During the last two years of his life Dr. D. saw him occasionally. He passed his water with difficulty, and was fully convinced that there was another stone in the bladder. To corroborate this opinion, Dr. D. attempted to pass an instrument, but was unable to pass even a No. 1 into the bladder through either urethra or sinus. He died in December, 1883, at the age of 55, of an apoplectic attack, eleven years after the passage of the stone. In addition to the sinus, which never entirely closed, a cicatrix, three inches in length, existed in the perineum.

Scattered through the older surgical works are to be found some cases where the stone has been found of great size, yet, as showing how uncommon they are, I may refer to the wonderful table given in J. G. Cross's prize essay, written in 1833, where a most accurate detail is furnished of sixty years' lithotomy operations performed in the Norfolk and Norwich Hospital. The cases in all amounted to 504, and of that large number there were only nine stones above four ounces in weight, and only two above six ounces, and in the last the patients succumbed. There was not a single lithotomy in which the stone weighed seven ounces in the entire sixty years' operations; in fact, on the whole, there are only a few instances on record of a successful result where the stone exceeded seven or eight ounces.

Kefir.

We take the following, by Dr. Edward Kern Moskwa, from the *Pharmaceutical Record*, May 1, 1884:

Kefir has been known outside of Caucasus only two years. Now it is known in Russia and has spread through Europe. At present you will find kefir factories in all large cities in Europe. Two years ago nobody knew kefir but the mountaineers in Caucasus. They were told that Allah himself had given his children of Islam a panacea for their sicknesses. And they kept this gift to themselves, because kefir would lose its beneficent effect if the unbelievers came into possession of it.

The secret is out, and now the therapy has acquired what no other remedy could perform, and no other remedy can show such remarkable results or be more welcome by the profession.

Before I describe how kefir is made, I think it necessary to give information about the ferment. This consists in peculiarly-formed globules, which generally are called Dispora Caucasica (Zoogloza) and cells of yeast (Saccharacomices cerevisiae).

Dr. Podwysotsky, in Kief, makes kefir by using cow's milk or goat's milk at 30–40° C. To this he adds compressed yeast and a pinch of natr. bicarb. Prof. Smidt, in Moskwa, has proven how by this expedient the casein and albumen is changed to semi-albumen, which stands between albumen and pepsin.

The milk and yeast to be filled in clean, well-corked bottles, these to be kept in a temperature not over 15° R., well shaken every two hours, and in seventy-two hours the kefir is ready for use. It will then be quite freely effervescent. Dr. Dmitrieff Jalta recommends kefir made from boiled milk, especially for children. Dr. Podwysotsky, in Kief, prefers kefir made of skimmed milk for all sicknesses from weak stomach. Dr. Sadoven, in Kasan, claims to have made an important discovery. He declares the milk-sugar is converted into carbonic acid, alcohol, glycerine, and lactic acid.

Dr. Sadoven gives as a result of his experiments:

Casein	2.5670	grains.
Albumen	0.7480	"
Peptone	0.0222	"
Sugar	1.5376	"
Alcohol	1.5	"
Acid lactic	1.3500	"

Kefir is a nourishment, not a drug. Kefir is nutritive, restorative, alterative; nervousness subsides, the stomach performs its work, and the body feels the effect through renewed energy. Besides, kefir is expectorant, diuretic, and sudorific.

In all pectoral ailments, even chronic pneumonia, kefir will act wonderfully. Generally the fever and the cough will disappear in two or three weeks' time, the sleep will be more quiet and uninterrupted, and the appetite better.

For bronchitis there is not a better remedy. Kefir will show its effect almost instantly. All serious disturbances of the stomach will be benefited, and in most cases cured by kefir. Kefir is to be taken regularly. Commence with a wineglassful a day. Then a glass and a half, increasing to six or eight glasses a day. In summer time it may be raised until twenty to thirty glasses a day. The time for using kefir is generally six weeks.

In some cases kefir will act toward constipation, which is easily prevented by the use of common laxatives. Dr. Soboleff recommends for pneumonia 5 grains pepsinum to every bottle. Dr. Podwysotsky uses in cases of anæmia one or two grains ferri lact. and ten grains sacchar. alb.

The Treatment of Seborrhœa.

Dr. George H. Fox thus writes in the *Nashville Jour. Med. and Surg.*, June, 1884:

If the systemic conditions which predispose to seborrhœa were better understood, much might be accomplished by attention to diet and internal medication. In the present state of our knowledge we are forced to rely mainly upon external treatment. There are two objects to be kept in mind in the treatment of every case, viz., to soften, if necessary, and to remove the sebaceous secretion, and to stimulate the glands to healthy action. The first aim can be readily accomplished; the second sometimes proves to be a difficult task. In seborrhœa oleosa the frequent use of soap tends to keep the skin dry, but rarely effects a permanent change in its condition. After bathing the skin with soap and hot water, and carefully drying it, the application of precipitated sulphur, tannic acid, or some other astringent powder, is

usually beneficial. If there be a tendency for thin crusts to form over the affected surface, the following ointment, lightly applied by means of the finger, is preferable:

℞.	Washed sulphur,	8 parts.
	Balsam of Peru,	2 "
	Petrolatum,	40 "

M. In obstinate cases of seborrhœa of the nose, and these cases are generally obstinate, I have obtained the best results by having the patient rub the nose vigorously before going to bed with a soft linen rag wet with ether, and then apply the following lotion:

℞.	Sulphate of zinc,	3 parts.
	Sulphate of potassium,	3 "
	Alcohol,	10 "
	Rose water,	100 "

M. In dry seborrhœa of the scalp the crust may be readily removed by soaking it thoroughly at night with olive or almond oil, and shampooing the head in the morning with the officinal tincture of green soap. This will leave the scalp clean and natural in appearance, but a cessation of the treatment at this point will be speedily followed by a return of the crust. The patient must therefore be directed to shampoo the head twice every week, or oftener if it seems necessary, and to apply meanwhile some slightly stimulating ointment every night. Hyde recommends the following:

℞.	Oil of sweet almonds,	10 parts.
	Carbolic acid,	1 "
	Alcohol to	100 "
	Oil of bergamot,	q. s.

M. If this plan of treatment is carried out for a few weeks, the tendency to the return of the crust will usually cease. In the many cases where seborrhœa does not form a thick crust upon the scalp, but occurs in the form of dandruff with the falling of the hair, it is often necessary to prolong the treatment for several months.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A convenient duodecimo of 166 pages, written by Dr. C. H. Leonard, has been published by the Illustrated Medical Journal Co., of Detroit, Michigan, on "Auscultation, Percussion, and Urinalysis" (price, $1.00). It is illustrated, and treats succinctly of physical diagnosis, the pulse, the sputa, the liver, spleen, and kidney, and the chemical and microscopical examination of the urine. Dr. Leonard is well known for his success in writing epitomes for the profession, and we do not doubt that his present venture will be equally successful with those that have preceded it.

——In a pamphlet entitled "Directions for the Antiseptic Treatment of Wounds, as Employed at Prof. Billroth's Clinic," written by Dr. Victor R. v. Hacker (published by Cupples, Upham & Co., Boston, price 50 cents), we have a very thorough exposition of the latest form of the German method of antisepsis. The principal agent employed is iodoform, which appears to have taken the place of carbolic acid in the fashion of surgery. The description of its employment is well worth perusal.

——A bulky pamphlet of nearly 400 pp., by Dr. Joseph Jones, gives an account of the quarantine and sanitary operations of the Board of Health of the State of Louisiana, between 1879 and 1884. It is closely printed, and full of information in reference to public hygiene. Dr. Jones is strongly in favor of a regular quarantine, and his arguments for it are sound and convincing.

——Dr. John S. Hough, of this city, has recently written an interesting essay entitled, "An Inquiry Concerning the Relative Influence of the Sex of the Fœtus in Utero on the Mental, Physical, Physiological, Pathological, and Developmental Condition of the Mother during Gestation, Lactation, and Subsequently." It is characterized by his usual erudition.

——Prof. J. S. Wight, M. D., of Brooklyn, in a recent reprint, urges that the proper treatment of criminals should be greatly mitigated, and made rather a matter of reformation and education than of punishment. It is our opinion that all such advice is foolish sentimentality, and has already been acted upon too far. Even now a brutal criminal is better cared for, better fed, and better clothed, than the majority of honest laborers. We already almost offer a premium for crime, and further urging in this direction is needless.

Solutions of Morphia for Hypodermic Use.

In the *Med. News*, February 10, 1884, we learn that Professor Hamburg finds morphine sulphate to be less prone to decomposition and to the formation of mycelia than the hydrochlorate and other salts, and therefore considers the sulphate best adapted for medicinal morphine solution. It should be dissolved in pure boiling distilled water, and the solution should be filtered through paper not previously moistened (Year Book of Pharmacy, 1882). Dr. Squibb has given us a *wrinkle* in the preparation of solutions of the alkaloids for such purposes as collyria and hypodermic injection. He says a few grains of salicylic acid in four ounces of water makes a solution in which alkaloids may be dissolved, and can be kept for years without the growth of fungi. The small amount of the acid used is without any physiological effect either when dropped in upon the eye or used subcutaneously.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

PATENT MEDICINE SUITS.

The vendors of patent medicines get into trouble frequently with each other, and their affairs are ventilated in court. These troubles are generally over the trademarks by which they label their wares, and a successful compound usually has many imitators trying to get into public favor through its popularity.

There was a case in the United States Supreme Court not long since by the manufacturers of what was called "Atwood's Quinine Physical Jaundice Bitters, Georgetown, Mass." It appeared that some persons in Portland, Maine, were imitating the concoction and also the label, and a suit was brought to prevent this.

On the trial it appeared that Atwood himself was dead, and that the medicine was not manufactured at Georgetown, Mass., but at New York, by the Manhattan Medicine Company. These statements were held by the court to be misleading to the public, and an injunction was refused against the Portland manufacturers, who were taking away the trade of the original makers. The ground of the decision was that any trademark must contain nothing but what was absolutely true, if it was desired to prevent outsiders from imitating it.

A still more recent case was that in a Maryland court, to prevent imitations being made and sold of the "Aromatic Bitters or Angostura Bitters, Prepared by Dr. Siegert, at Angostura, now Port Spain, Trinidad."

It was shown by the evidence that Dr. Siegert had never lived at Angostura, and had been dead some ten years. After his death, a firm was formed for the purpose of manufacturing his compound, and the place of business was changed to Port of Spain, but the statement was still kept on the labels that the medicine was manufactured by Dr. Siegert.

These statements were also held to be misleading and false, so that the aid of a court of equity would not be granted to prevent any imitations.

It would seem from these cases that the manufacturers of quack medicines and nostrums of

more or less vileness do not always have a perfectly easy time in gulling an unsuspecting public. Whenever a patent medicine gets a name and trade for itself, at once a host of imitations spring up, and suits are begun over the trademarks.

THE SPLEEN AND THE THYROID GLAND.

At the XIth Congress of the German Society for Surgery, Dr. Credé, of Dresden, presented a patient whose spleen he had removed about a year previously. The cause of the operation had been cystic degeneration of the spleen; the patient, æt. 44, had rapidly become convalescent, and he was introduced to the Congress as a perfectly healthy individual. Two months after the removal of the organ, Prof. Birch-Hirschfeld examined the blood of the patient, and found that the ratio of the white corpuscles to the red was as one to three. Five months later the blood was nearly normal. Credé reported that the most interesting observation that he had made on the patient had been the enlargement of the thyroid gland, occurring in the fourth week after the operation, and continuing until the middle of the fifth month, when the swelling decidedly diminished, but a small goitre being still observable. Credé obtained the following result from his investigations of the case. The function of the spleen consists in the metamorphosis of the white globules developing in the lymphatic system to red corpuscles, which latter, in the blood of spleenless animals, have been noted as being of diminished size.

Zesas, in his experiments, not only adhered to the same view, but he also proved that in cases of extirpation of the spleen, some other glandular organ had to assume the blood-making function of the spleen. His conclusions were these: When in a human being or in an animal the spleen is removed, leucocythæmia first develops itself. Then glandular enlargements ensue, and after a certain period one gland alone stays enlarged, while the blood slowly resumes the normal relationship of its blood corpuscles. Quoting Credé's case and some others published before and after it, Zesas believed the thyroid gland to be the organ which exerts the function of the spleen, when this is extirpated.

Recently, Dr. Tauber (*Allg. Med. Centr. Zeitung*, April 16, 1884,) has instituted a series of experiments. The result has been such that the assertions of Credé and Zesas are denied by Tauber, who has proven that in animals both the spleen and the thyroid gland may be extirpated without any other influence on the blood than that exerted by the removal of the spleen alone; that the thyroid gland does not assume the blood-making functions of the spleen, and that the latter can be considered only a reservoir for the blood.

THE SEAT OF HYSTERICAL APHONIA.

Those cases in which suddenly loss of voice developed itself, as for instance in cases of hysteria, and in which no lesion of the larynx can account for the symptom, have never been explained. It is possible that recent experiments by Krause (*Berl. Akad. Sitzb. Centralbl. f. d. Med. Miss.*, 15, 1884,) may bring us near the final solution of the question.

By electrical excitation of the anterior perpendicularly descending surface of the gyrus præfontalis in the dog, K. obtained, besides contractions of the anterior muscles of the neck and ascending of the larynx, motions of swallowing, lifting of the velum, contractions of the superior pharyngeal constrictor, of the posterior part of the back of the tongue and of the arch, and a partial or total closure of the glottis. Sometimes, when the electrodes were in a certain position, the vocal cords were in the so-called cadaver-position.

But when K. removed the cortical part of the gyrus præfontalis on both sides, some animals lost the faculty of barking, others succeeded in bringing forth only a kind of screeching sound, or powerless high tones, while it was apparent that they made use of a great amount of air and a great effort to produce even these sounds.

Of this gyrus fibres descend by the crus of the same side; in these, eight to eleven weeks after the operation, whole parts of axis cylinders and degeneration of others were noted. The tedumulus corporis mamillaris also appeared diminished

in size, and in the Vicq d'Azyr bundle of fibres, and still more in the root of the fornix, a divided loss of substance was observed in the fibres. These parts must therefore belong to the tract of fibres starting from the gyrus præfontalis and descending, reaching finally the larynx.

How the centre for the sound of the voice is deprived of function in cases of aphonia, cannot be easily explained, as in some animals even the destruction of the part still permits a sound to be uttered. But it is probable that anæmia, or otherwise the cutting off of the supply of blood to a certain extent, may cause the cessation of function.

SPASM OF THE SPLENIUS.

A lady suffered for a year from contracture of one splenius muscle. Cure was established by Dr. Adamkiewitz (*Wiener Med. Presse*, 48, 49, '83), with methodical faradization of the apparently healthy splenius muscle of the opposite side. The result demonstrated that the *apparently* healthy muscle was in fact the weaker, and the splenius muscle, which was *apparently* diseased, had simply disturbed the equilibrium by its normal contraction, not balanced by the healthy function of its partner on the other side.

We think that, if not in all, at least in most cases of long-continued muscular contracture (spasmodic contraction), it is not the contracted muscle which is the seat of the morbid lesion, but its antagonist, which is diseased, has become weaker, and thus gives rise to the increased abnormal contraction of the other healthy muscle. We have never seen any good result from the galvanization of a contracted muscle; but Benedict, whose experience was great in these complaints, always recommended the galvanization of the contracted *and* the faradization of the opposite muscle, giving as his reason for so doing, that faradization would irritate but more the hyperexcited muscle. But if it is true that galvanization has no effect in removing the apparently abnormal contraction, while faradization greatly increases the power of a weakened muscle; and if we adopt the theory that in all such cases the not-contracted weaker muscle on the other side is the one diseased, the whole at once becomes clear. Two muscles, one on each side, exert, we will say, a certain amount of traction. If one becomes diseased and weakened, giving no indication of its function, the other will appear to have doubled its action. Naturally in such a case, strengthening (faradization) of the weaker muscle will reestablish the equilibrium. These cases can at least not be otherwise explained. We would advise, therefore, in all cases of contracture of a muscle (as in torticollis), to leave the contracted muscle alone, and to faradize and otherwise strengthen its antagonist on the other side.

LET US HAVE THE TRUTH.

Now that an epidemic threatens our shores, it is timely to say a word in favor of truth-telling.

There is always a party who want to lie, and to persuade physicians and health officers to lie, about the existence or the severity of an epidemic disease in a city—their real motive is the meanest selfishness. Their asserted motive that it is unwise to alarm the public, etc.

In fact, every consideration of sound sanitary science, as well as morals, condemns the concealment of epidemic sickness or the falsification of reports about it. There is certain to be a public rumor about it, and this is certain to be exaggerated.

Let the public be taught confidence in the candor and the skill of its boards of health and sanitary authorities. Let there not be the slightest effort to obscure a diagnosis or to conceal a case. Private and commercial interests should count for nothing, as against scientific candor.

There is a fair prospect that this summer at least we shall not have a severe infliction of an epidemic. But should it appear, let the utmost publicity be given its march.

NOTES AND COMMENTS.

Bright's Disease of Malarial Origin.

Dr. I. E. Atkinson, of the University of Maryland, believing that this subject has not attracted

the attention it deserves, has been led to study with reference to it all cases of malarial fever coming under his observation during the late summer and early fall of the past two years, at Bayview Asylum, and the result he gives in an able and elaborate paper which appears in the July number of the *American Journal of the Medical Sciences*. The conclusions which he reaches are as follows:

1. Transitory albuminuria is not uncommon in the course of malarial fevers, and is due to the intense visceral congestions characteristic of these affections. It only may endure throughout the height of the congestion, recurring with each return of this, or it may persist in the intervals, in which event a higher grade of congestion is attained, more nearly approaching a condition of acute inflammation.

2. In a proportion of cases varying with locality and type of prevailing epidemic, or individual conditions, inflammation of the kidney occurs, accompanied by dropsy and the usual symptoms of nephritis.

3. The usual form of malarial nephritis is the tubal and diffuse variety. In this the inflammation seems to be most intense in the vicinity of the glomeruli.

4. Contracted kidney may occur as an advanced stage of malarial nephritis, either from long-continued or frequently repeated attacks of malarial fever, or from fibrotic changes such as may ultimately occur in ordinary tubal or diffuse nephritis. It is altogether improbable that this form of malarial renal disease ever occurs primarily as purely interstitial nephritis.

5. These changes may be induced by any form of malarial fever, though they more commonly follow chronic intermittent fever.

6. The tendency of malarial inflammation of the kidney is toward recovery. But from the persistence of the impaludism or the intensity of the inflammation, structural changes may be produced that are characteristic of chronic Bright's disease, when the gravity of the affection will be as that from chronic Bright's disease, from whatever cause.

7. Treatment should be directed primarily against the malarial intoxication, more especially in recent cases. A correction of this will often be followed by a complete, though often gradual, subsidence of the nephritis. Even in more chronic cases, the malarial factor in the process should definitely be destroyed if possible, after which the disease should be treated as ordinary Bright's disease.

Etherization by the Rectum.

Commenting on this newly-recommended procedure, the *London Medical Times*, May 24, 1884, says that Dr. Yversen's proposal to anæsthetize patients *per rectum* appears likely to have a future. It is claimed that the method is as safe, and as effectual, and not so unpleasant to the patient, as the ordinary method of inhalation. On Dr. Yversen's proposal, Mons. Mollière, of Lyons, tried it in various operations, and with so much success as to encourage the best hopes of its proving really useful. Since the publication of the method, other surgeons appear to have tried it, and in many instances with satisfactory results. The plan of administration is to connect an India-rubber tube with the ether bottle, and to the other extremity a vaginal nozzle is attached, which is introduced into the rectum. The bowels are thoroughly cleansed with a preliminary purge, and the rectum is emptied by an enema shortly before operation. When all is ready, the ether bottle is placed in hot water of 140° to 160° F., the temperature varying a little with the amount of ether vapor required: the heat of the water must be kept up. The time required to produce complete anæsthesia appears to vary from six to thirty minutes, and the amount of ether used from two to six ounces. The distension of the bowels with ether vapor appears not to cause any great discomfort: it is quickly absorbed, and can be detected in the patient's breath within a few minutes of the commencement of its exhibition. The period of excitement, which M. Mollière thought was not experienced, appears, however, to be present in many cases; and a fact also not noticed by him, is the occurrence of diarrhœa in a considerable proportion of cases. In one or two, the diarrhœa has been accompanied with the passage of blood, and in one child it is reported that death resulted on the day following the operation, after several large and bloody stools had occurred. It is well, therefore, that surgeons should be put on their guard. Doubtless, experience will soon teach whether the diarrhœa is accidental, or due possibly to the mode of administering the ether —perhaps, too, a too rapid distension of the bowel with the ether vapor may have to do with it. It must be remembered that the ether vapor once introduced into the intestines cannot be easily withdrawn; and until, therefore, its effects are better known, great caution must be used. The anæsthesia must be produced slowly, that is, the ether must not be placed in too hot water. We shall hope to receive reports as to its mode of action from those who try the method.

A Case of Left Inguinal Colotomy for Imperforate Rectum.

Dr. W. H. Haynes, of New York, records in the July number of the *American Journal of the Medical Sciences* an interesting case of inguinal colotomy. One procedure in the treatment we do not find discussed elsewhere in detail, namely, that of opening up a passage at the natural site for the canal, either simultaneously or subsequent to the operation of opening the gut. When the two operations are to be performed at the same time, the first or inguinal opening would be in the nature of an exploratory operation, and should be made small so as to admit of immediate closure and return to the peritoneal cavity, after a passage had been secured at the natural site. If this latter be not secured, then the opening could be enlarged and made to serve the purpose of an artificial anus in the abdominal wall. The advisability of this procedure, however, is at present in such a doubtful state, that only the experience of a number of operators can determine it. Of the few cases so far undertaken in this manner that Dr. Haynes can find recorded, his own is the only one that survived the second operation.

Dr. Haynes' single experience, though successful, does not lead him to advise this procedure, since the object of it will, during the early years of its life, be dependent on the exceedingly diligent and constant attentions of others whose affections and services, though the closest, are not to be depended on, as was demonstrated in his case. If the second operation be subsequent to the first, the patient will have a double annoyance, or be under the necessity of having a third operation performed by the closure of the opening first made, which is not unattended by danger to life, or by doubts as to the result; and perhaps be under the necessity of having to have it reopened, owing to neglect in the proper after-treatment of the new canal in the natural site. Whereas, if one is satisfied with having saved life in a manner which numerous cases testify is not unenjoyable or full of discomfort, as used to be maintained, all dangerous risks of subsequent operations are avoided, there will be no more dependence on others' services than is natural, and many sources of distress that natural flesh is heir to will be obviated.

The Treatment of Diphtheria.

Dr. J. W. Moore says that in his hands the following line of treatment, which he publishes in the *Med. Annals*, June 1, 1884, has been almost uniformly successful in the cases that he has treated during the past six months, the rate of mortality being two to thirty, these two dying from fibrinous tracheo-bronchitis. After attending to the hygienic necessities as far as possible, such as putting the patient in a well-ventilated room, the air of which is both warm and moist, with the temperature between 60° and 65° (assuming that we are able to put our patient in a comfortable room, as often we have to treat them as we find them), and thin patches of false membrane presenting themselves, with other concomitant symptoms, he gently sprays the throat with a weak solution of chlorine gas, made by the action of tr. chlor. iron on potassium chlorate, slowly adding water as the chlorine is given off. He then gives, according to age, from ten to fifteen drops of the tr. of iron every three hours in a little glycerine and water; good nourishing diet, such as milk, eggs, etc. On the second day, if the disease is not checked, he gives one drop of Lugol's solution of iodine, and a half drop of carbolic acid, in a little water and glycerine, every two hours, and increases the intervals of the iron to four or five hours. He also uses a direct application, discarding the spray, of a mixture of iodine, glycerine, and carbolic acid.

Tubercle-Bacilli in Tonsils.

About thirty years ago the observation was first made that children suffering from chronic tonsillitis or from other chronic enlarged glands of the neck are apt to become the victims of tubercular consumption of the lungs when they reach the twentieth year, or thereabouts. About ten or fifteen years ago a German surgeon first recommended the extirpation of these glands as a preventive of phthisis. He had made the observation that children, in whom such enlarged glands suppurated and thus died, were exempt from phthisis. And, indeed, statistics published only some two or three years ago, proved that children in whom the preventive operation had been made not only enjoyed later the best of health, but also ceased to be scrofulous.

We now have an explanation of the good results following the operation, and of the fact that children, in whom such glands suppurated of their own account, reached a high old age. Dr. F. Strassmann (*Virchow's Arch.*, 96, vol. ii., 1884,) has examined a number of such enlarged glands, and found them filled with tubercle bacilli. He besides proved, that in cases of tubercular phthisis of the lungs the tonsils also became the seat of the same disease, and he believes that the infection in such cases takes place by the saliva.

This gives us an explanation of another fact, viz., the common occurrence of "sore throat" and enlarged tonsils (due to which is the hawking of such patients) in tubercular patients.

The Heroic Use of Calomel in Diphtheria and Croup.

Since we have had occasion recently to refer to this method of treatment, it affords us pleasure to see the suggestion therein noted very strongly endorsed by Dr. J. P. Klinginsmith, of Blairsville, Pa., who writes about it to the *Med. Record*, July 12, 1882. The mercurial used in these cases was the English calomel, and was given by filling a teaspoon half full of cold water, then dropping the medicine upon it, after which it was placed well back in the mouth of the patient. The calomel purges, but not to excess, causing simply free and copious evacuations of a greenish appearance. He has never known ptyalism to occur in a single case. His experience with this plan of treatment is based upon three cases of his own, besides a number occurring in the practice of other physicians. He believes that with a faithful and proper administration of the remedy in question, disintegration and separation of the membranes will be facilitated, as well as relief afforded to allay the spasmodic character of the disease.

In this connection it will be interesting to note that Dr. Hanks reports to the New York Obstetrical Society that he has for two years been employing minute doses of corrosive sublimate internally in the treatment of diphtheria in children, and believes that he has obtained better results thereby than by the use of any other medicine.

Universal Erythema After the Use of Sublimate-Gauze.

As an antiseptic dressing, especially in Germany, gauze saturated with a corrosive sublimate solution ($\frac{1}{1000}$) is now employed to a great extent. Dr .Reichel, who has often noticed local irritation follow the application, reports in the last number of the *Berl. Klin. Woch.* the following case:

A baker, æt. 22, had, on account of left genu valgum, osteotomy performed. The leg was bandaged up from the ankle to the groin with sublimate-gauze. Five days later, a burning sensation set in, which so increased that on the ninth day the dressing had to be removed. An intense, papulo-vesicular eczema was found, and this was complicated by a general erythema, covering the whole body save the face and neck. The sublimate-gauze was exchanged with salicylic-dressing, and no further attention paid to the erythema, which disappeared within a few days.

Local eczema is not rare, but such general irritation of the whole skin has never been observed from the application of sublimate-gauze.

Examination of the Air for Microzymes.

For this purpose, Dr. Hesse, of the German Imperial Board of Health, recommends the following procedure: A fine glass tube, which at its upper end has a fine opening, and which at its lower end can be closed by a sterilized cotton-stopper, is first exposed to a sufficient heat to insure its sterility. Then sufficient aseptic gelatine is poured into the glass tube to slightly cover the inner side. The air to be examined is drawn (from a room, the open air, or anywhere) by an aspirator, and slowly blown by the same instrument through the fine opening on top of the tube, the air slowly passing out at the lower end, where a fine opening is left in the cotton-stopper. The passage of the air through the tube causes a deposit of its microzymes on the gelatine-coated inner surface of the tube, which is then closed. Later, a microscopical examination, if necessary, controlled by pure-cultures, demonstrates the varieties of microzymes present in the examined air. The procedure is very simple, care only having to be taken that every implement used is aseptic, and that no other air can enter the tube, which can, however, be easily prevented.

Stretching the Spinal Cord.

From a foreign exchange we learn that Prof. Hegar has recently read a paper at Freiberg in which he advocates stretching the spinal cord. Our readers will be glad to hear that the operation does not consist in opening the spinal canal and directly stretching the spinal medulla. But Dr. Hegar has found that when the spine is very much bent the cord is actually lengthened. His mode of procedure is to place the patient on his back, and then, with the knees kept carefully straight, the lower limbs are bent up towards the chin as far as possible. In this way the great sciatic nerves are put on the stretch, and this, as well as the over-bending of the spine, stretches the lower end of the cord. The cases for which Dr. Hegar recommends this treatment are those of women who suffer from pelvic pain, and of nervous phenomena referable to the branches springing from the lumbar enlargement of the cord. Already the treatment has been employed in a few instances, and, it is stated, with success.

Extirpation of the Clitoris.

Though of late somewhat come into discredit, the following case of Engelman shows the advantage, as occasionally met with, of clitoridectomy:

A woman, æt. 52, suffered during the climacterium from the following symptoms: Pruritus vulvæ et vaginæ, sensation of congestive flow of blood from the external genitals to the spine and the occiput; profuse sweats, disturbances of the stomach, icterus, vomiting. Besides these symptoms, which were permanently present, the patient also complained at times of hyperæsthesia of the genitals, tremor, vertigo, headache, insomnia, inability to work, and *tædium vitæ*.

Vulva and vagina being hyperæmic, carunculæ myrtiformes congested, labia minora and clitoris hypertrophied, and the least touch of the clitoris causing a seizure and aggravation of all symptoms, and the urethra being the seat of very painful carunculæ, Dr. Engelman partially extirpated the clitoris and destroyed the caruncles. An immediate and great improvement set in, and thus encouraged, E. totally extirpated the clitoris and the hypertrophied labia minora. The result was excellent. No untoward symptom followed the operation, and every indication of disturbed health ceased. Six months later, the patient had no complaint whatever, and enjoyed the very best of health. Masturbation generally prevents the good results of the operation, and is the cause of all relapses. (*Allg. Deut. Med. Centr. Z.*, 520 p., 1884.)

Neuralgia in Diabetes.

Besides the usual forms of neuralgia, which are met with in diabetes, peculiar neuralgic pains often set in, which seem to stand in intimate connection with the malady in question. Worms, Berger, Raymond, and others, have specially inquired into these neuralgias, and they had come to the conclusion that the quantity of sugar excreted bore a direct relation to these pains. Cormillion (*Journ. de Méd. de Paris*, 13, 1884,) has recently again taken up the subject, and from a large number of observations he makes the deduction that while these neuralgias doubtless become worse with every aggravation of the diabetes, and improve with every amelioration of the original disease, the quantity of sugar excreted has little influence in that respect, but it is the general condition of the patient, which, in diabetes as well as in other maladies, decides the degree of severity in the complications.

The neuralgias of diabetes have the peculiarity of always being symmetrical. Of twenty-two cases, eighteen happened on both sides. Most frequently the sciatic nerves suffer. There is no special treatment necessary, as the general treatment, which influences the diabetes, also improves the neuralgia.

The Water-Cure in Diphtheria.

Dr. Gasparini (*Gazz. Med. Ital. Lomb.*, February 16, 1884,) accepts Morell Mackenzie's definition of diphtheria, and looks upon it as an acute infectious general disease, with a tendency to the production of certain local manifestations. His treatment consists in wrapping the patient in a cold wet sheet, repeating the packing three or four times a day, according to the height of the fever. Cold compresses are to be kept continually to the throat. He also uses gargles of the alkaline sulphites, carbolic acid, etc., as disinfectants, never caustics. In 1875 six cases were thus treated; all recovered, the disease lasting from five to eleven days. In 1879 seven cases recovered under the same treatment, the average duration of the disease being ten days. This treatment is well borne, and the patients like it; its antipyretic action is marked, though transitory. Stimulants are at the same time to be freely administered. The duration of the disease is not influenced; but convalescence is shortened and the strength is more quickly recovered.

Nephritis and Varicella.

Chicken-pox is usually considered a very mild disease. Text-books say that occasionally death takes place by that disease, but the cause has never been explained. The celebrated authority on diseases of children, Prof. Henoch, in Berlin, has discovered that nephritis occasionally complicates varicella. (*Berl. Klin. Woch.*, 1884, 2.) He observed in four children, eight to fourteen days after the beginning of the varicella, the development of acute nephritis. Three of the cases recovered, but the fourth died in consequence of rapidly-developing œdema of the lung. It shows that chicken-pox is not always the innocent disease which we believe it to be, and that we had better watch every case with the same care as we do in scarlatina. It may be safer near the end of the disease to examine daily the urine, as an early treatment of the dreaded complication will insure its favorable issue.

On Muscular Hypertrophy of the Stomach.

Concerning this rare condition of the stomach there appears to be but little known, and it is not

generally mentioned by writers on diseases of this organ; therefore the careful report of a case by Drs. Alex. Marcy, Jr., and J. P. Crozier Griffith, of Philadelphia, which appears in the *American Journal of the Medical Sciences* for July, 1884, has a special value. Unfortunately, the disease is rather of pathological than clinical interest, since there are no symptoms which are as yet known to be peculiar to it, and the treatment can only be palliative.

Solution of Iodoform for Injection in Acute or Chronic Blennorrhagia.

The *London Med. Record*, April 15, 1884, tells us that Campana gives the following formula:

℞.	Iodoform,	20 grammes.
	Carbolic acid,	0.10 to 0.20 grammes.
	Glycerine,	80 grammes.
	Distilled water,	20 grammes.

At first one injection only is to be used in the twenty-four hours; after three or four days, two injections daily. After about ten days, when the inflammatory symptoms have subsided, sulphate of zinc in mucilage and water is to be substituted for iodoform.

A Case in which Four Inches of the Shaft of the Femur were Lost by Necrosis, with Complete Recovery.

Dr. John Ferguson, of Toronto, reports this very interesting case in the July number of the *American Journal of the Medical Sciences*. Upon the removal of the sequestrum, which embraced the whole diameter of the femur, a thin shell of newly-formed bone was felt, and the steps of repair advanced until the femur was completely reformed without shortening. An expectant and tonic plan of treatment was adopted throughout.

Correspondence.

Dr. Hazlett's Case of "Facial Erysipelas," and its Maniacal Complications.

Eds. Med. and Surg. Reporter:

The practitioner who relates a given case and confesses his perplexity with reference to its features, and asks suggestions respecting their nature, deserves well of humanity and the respect of his brother practitioners: for it is through the rectification of error that truth is often established.

Dr. J. C. Hazlett, of Belle Vernon, Pa., gives a striking portrait of a case that occurred to him, with the treatment employed in it. With the same candor with which the doctor has submitted his case, I offer a few remarks concerning it. Of the original disease, not much need be said. Dr. Hazlett saw the patient, a lady in the very last period of gestation, at noon, on Saturday, March 1, "finding the face much swollen and inflamed, * * tongue heavily coated, throbbing headache. Temperature 101° F.; pulse 100." Let us see what the medical man gave her—"4 grs. of quinine s. every four hours"—equal to 24 grains per day; "also tr. aconite, fl. ext. belladonna, āā gtt. j., per hour"—equal to 24 drops of tinct. aconite and 24 drops fluid extract of belladonna per day. It is not stated whether these liquids represented the leaves or the root of the drugs, the prescriber probably not having read the following caution, under tinct. aconiti radicis, in the thirteenth edition of U. S. Dispensatory, "that physicians should be careful, in prescribing either of the tinctures of aconite, to give the whole name of the one they intend, as otherwise serious consequences may ensue."

The record continues: "Sunday, March 2, 3 a. m., a good-sized boy had been born about one hour." The doctor did what was needed for the patient's comfort and well-being; and, "continued the same treatment as the day before." He had "found temperature normal, pulse 100, patient free from pain and resting easy"—a condition which would suggest little treatment. Record continues: "Saw patient at 5 p. m. Temperature 100½°, pulse 100; appetite good. Continued quinia sulph., 4 grs. every four hours" (24 grs. per day). * * * "Continued aconite and belladonna every hour or two" (12 to 24 drops each per diem).

"Monday, March 3, 7 o'clock a. m. Temperature 101⅘°, pulse 100. Continued treatment of the day before, and saw her again at 5 o'clock p. m., and found temperature 102⅘°, pulse 100, appetite good, swelling and flush beginning to fade and pass away.

"Tuesday, March 4, 11 o'clock a. m. Temperature 102⅗°, pulse 96; 5 p. m., temperature 104⅕°, pulse 86, appetite good, but *complains a little of dryness of the throat.*

"March 5, 9 o'clock a. m. Temperature 99½°, pulse 80. Erysipelas entirely gone; *throat still dry, pupils a little dilated.*"

Nothing is said of the treatment of Tuesday, March 4, but we may fairly infer that it was the same as on the preceding days. At this time, March 5, a consultation is held, and the record says: "We stopped all active treatment, and gave quinia sulph., grains iv. every six hours" (16 grains per day).

"At this time my patient began to talk a little incoherently, but was not stupid, and recognized any one on going to her bed. Saw her again at 5 o'clock p. m. Temperature 99⅘°, pulse 80; *mouth still dry;* inclines to talk, also to look and listen as if for some one calling; then will speak to some imaginary person on the bed, or at the foot of the bed, or call to some of the children that are in danger, or in mischief, sometimes kindly, but generally in great earnest."

"Thursday March 6. Was called at 5 o'clock a. m. Patient much worse. *Temperature normal; pulse normal*, but very restless and wild; had put in a fearful night, raving, crying, scolding, and pleading to be taken home. Her night-clothes and underclothes, together with the sheet, were completely saturated with perspiration. She had passed no urine, but no accumulation could be detected. Gave potassic bromide gr. xv.; chloral

hyd., gr. v., every half hour until sleep was produced.

"6 o'clock p. m. Temperature, 97° F.; pulse, 76; has taken potassic brom. ʒiij., chloral hydrat. ʒj., during the day, but no signs of sleep. * * Is very wild, talks incessantly to imaginary persons about her, and frequently speaks of explosions that are taking place, even brushing the dirt from the bed-covers as it falls about her. Does not recognize any one except her father. No urine passed during the day, and much against my patient's will, with the assistance of four women, I used the catheter, and drew off about thirty ounces of not unhealthy urine. Continued chloral and brom. and to each dose added about one-eighth grain morph. s., staying with my patient until three doses were given, watching the effect. At this time she ceased to talk so much, and would lie still a few minutes at a time. * * At 10 o'clock p. m., she slept, and continued to sleep most of the time till morning.

"Friday, March 7, 8 o'clock a. m. Found her *at home*, calm, and in her right mind, but extremely weak."

We must now return to 9 o'clock a. m., of Wednesday, March 5. If we recall the fact that for nearly four days the patient has been taking from 10 to 15 minims per day of fluid extract of belladonna, somewhere from 40 minims to one fluid drachm in all, and a considerable amount of tincture of aconite, we shall be able to find a very probable reason for the cause of the hallucinations, the fierce delirium, the great sweatings, and the suppression of urine. The view that this was a case of belladonna poisoning is strengthened by the fact that while potassic bromide and chloral were exhibited ineffectually for thirteen consecutive hours, complete relief was obtained by $\frac{3}{5}$ gr. morphia s., distributed over about four hours. In the morning, the same medicine having been continued during the night, the lady was "At Home," much to the delight, no doubt, of all.

I append a few notes from standard authors, which place in relief the symptoms of belladonna poisoning.

Von Boerck (Ziemssen's Cyclop., art. Atropia, p. 666), after relating the usual early symptoms, thus tersely states the phenomena when fully developed: "Giddiness, headache, slight stupor, confusion of mind, dejection; to these are added hallucinations of sight and hearing, various in character, often of a cheerful nature, * * * then follow in most cases difficulty in micturition," etc. Again, on page 669: "The first symptom is generally giddiness, swimmings in the head, abnormal sensations, especially of sight and hearing; hallucinations are also very common, and delirium is superadded, so that the general condition may be characterized as one of mental aberration with delirium."

Pereira (Mat. Med., vol. ii., art. Belladonna, p. 472), enumerates among many other symptoms of poisoning in the second degree: "Visual illusions (phantasms), suffused eyes, occasionally disturbance of hearing (as singing in the ears), numbness of the face, confusion of the head, giddiness and delirium, which at times resembles intoxication." In the third degree he mentions "continual motion of hands and fingers, gay delirium, with a vacant smile."

Dr. Wood (U. S. Dispensatory, xiii. edition, art. Belladonna, p. 170) enumerates as symptoms, "vertigo, and intoxication or delirium, with violent gestures, and sometimes fits of laughter." According to the same author, the dose of the powdered leaves is for adults one or two grains, repeated daily or twice a day, and gradually increased till the characteristic effects are experienced."

On the effects of belladonna on the human subject, I again quote from Boerck's article in Ziemssen's Cyclop.: "As a general rule belladonna and atropia are very powerful poisons, even in very small quantities. In a case given by J. Seaton, one single nightshade berry was sufficient to produce severe symptoms of poisoning in a young man." The same author says: "The German pharmacopœia fixes as maximum doses of belladonna leaves, per dose grains 3; per diem grains 9." As to the liability of accumulation, we may get a hint from the same paper (p. 685): "When the dose of atropine has been large, its effects will survive those of moderate doses of opium or morphine."

It may be proper to state that one drop of fluid extract is believed to equal one grain of the leaves, and that the effects of opium often last for many hours.

E. T. Blackwell, M. D.

Cedarville, N. J., June 25, 1884.

Syrupus Acidi Hydriodici.

(*Syrup of Iodide of Hydrogen.*)

Eds. Med. and Surg. Reporter:—

During an experience of several years, I have thoroughly tested this preparation in acute inflammatory rheumatism, chronic bronchitis, and scrofula. In the first disease I prescribe for adults from two to three teaspoonfuls every two or three hours, in a wineglass of water, during the febrile stage, until relieved; this, in my experience has always occurred within forty-eight hours. I then reduce the dose to one teaspoonful, and continue for five or six days at longer intervals. I have never observed any heart complications under this treatment, the remedy preventing exudation and organization of plastic material.

In chronic bronchitis, its effects have been very gratifying, not only affording prompt relief to the cough, but also to the secondary symptoms of asthma, which is so apt to occur in these cases, I prescribe from one to two teaspoonfuls three times a day, in water.

In scrofula and other cases requiring the alterative action of iodine, a teaspoonful three times a day, in water, will be found to act much more satisfactorily than potassium iodide, as it agrees with the stomach, and does not disturb the appetite; if anything, it increases it, and instead of depleting the system seems to possess tonic properties.

It acts admirably in syphilis; in combination with biniodide of mercury, its use can be continued for a long time without any unpleasant effects.

I would also speak of the success and peculiar

fitness of this remedy in lead poisoning and paralysis resulting therefrom, as it is the true theoretical antidote to this condition, converting the lead in the system into its iodide, which, owing to its solubility, is readily eliminated through the various excretory channels.

The non-irritant character of this preparation, its prompt action, and its palatability, very strongly recommend it to favor.

The syrup I have used is that prepared by R. W. Gardner, of New York.

JAMES CRAIG, M. D.

Jersey City, N. J.

NEWS AND MISCELLANY.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, April 1 to June 30, 1884.

Bailhache, P. H., surgeon. Detailed as chairman of Board to examine candidate for appointment into the Revenue Marine Service, May 17, 1884.

Vansant, John, surgeon. To proceed to Empire City, Oregon, as inspector, April 2, 1884.

Hutton, W. H. H., surgeon. Granted leave of absence for twenty-five days, May 14 and June 9, 1884.

Miller, T. W., surgeon. Granted leave of absence to attend the meeting of the American Medical Association, May 1, 1884. To proceed to Pittsburgh, Pa.; Ashtabula, Ohio; Buffalo, N. Y., and Detroit, Mich., as inspector, May 10, 1884.

Wyman, Walter, surgeon. To proceed to Crisfield, Md., as inspector, April 11, 1884. Detailed to represent the Marine Hospital Service as delegate to the American Medical Association, April 17, 1884. Detailed as President of Board for Physical Examination of Candidates for Appointment as Cadets in the Revenue Marine Service, May 20, 1884. To examine cadet graduates Revenue Marine Service as to physical qualifications, May 31, 1884. Detailed as member of Commission to inspect United States buildings at quarantine station on the Delaware river, June 16, 1884.

Austin, H. W., surgeon. Granted leave of absence to attend the meeting of the American Medical Association, May 2, 1884.

Gassaway, J. M., surgeon. When relieved by Passed Assistant Surgeon Mead, to proceed to Portland, Maine, and assume charge of the Service, April 16, 1884. Granted leave of absence for thirty days, May 28, 1884.

Stoner, G. W., passed assistant surgeon. When relieved by Surgeon Gassaway to proceed to Cairo, Ill., and assume charge of the Service, April 16, 1884. When relieved by Surgeon Gassaway, to report in person to the Surgeon General, June 20, 1884.

Irwin, Fairfax, passed assistant surgeon. Granted leave of absence for twenty-one days, June 19, 1884.

Mead, F. W., passed assistant surgeon. When relieved by Assistant Surgeon Devan, to proceed to Philadelphia, Pa., and assume charge of the Service, April 16, 1884. Detailed as recorder of Board for Physical Examination of Candidates for Appointment as Cadets in the Revenue Marine Service, May 20, 1884.

Carter, H. R., passed assistant surgeon. To inspect unserviceable property at the San Francisco Hospital, May 24, 1884.

Wheeler, W. A., passed assistant surgeon. To inspect unserviceable property at the Chicago Hospital, May 24, 1884.

Benson, J. A., passed assistant surgeon. Granted leave of absence for thirty days, April 14, 1884. When relieved by Passed Assistant Surgeon Stoner, to report to him for temporary duty, May 19, 1884.

Banks, C. E., passed assistant surgeon. Detailed as member of Board to Examine Physically Candidate for Appointment into the Revenue Marine Service, May 17, 1884. To inspect unserviceable property at Baltimore, Md.; New York, N. Y., and Boston, Mass., May 26 and June 2, 1884.

Bennett, P. H., assistant surgeon. Granted leave of absence for twenty days, June 28, 1884.

Devan, S. C., assistant surgeon. To proceed to Port Townsend, W. T., relieve Passed Assistant Surgeon Mead, and assume charge of the Service, April 14, 1884.

Urquhart, F. M., assistant surgeon. Granted leave of absence for thirty days, May 22, 1884.

Yemans, H. W., assistant surgeon. To report to Capt. M. A. Healey for duty as medical officer during cruise of revenue cutter "Corwin," April 16, 1884.

Glennan, A. H., assistant surgeon. To proceed to Mobile, Ala., for temporary duty during sickness of Passed Assistant Surgeon Goldsborough, June 17, 1884.

APPOINTMENT.

Brooks, Stephen D., M. D., of Massachusetts, having passed the examination required by the Regulations, was appointed an assistant surgeon by the Secretary of the Treasury, May 15, 1884. (Dr. Brooks had previously served as an acting assistant surgeon from March, 1883, to May, 1884.)

Report of the Meeting of the Adjunct Montgomery County (Pa.) Medical Society,

BY DR. J. B. CARRELL, HATBORO, PA.

The society met at the office of Dr. Carrell, and was called to order by the president, Dr. John Pason. The secretary being absent, Dr. O. C. Robinson was appointed secretary *pro tem.* After the usual routine business, Dr. Coltman, Jr., read a selected article on anæsthetics, from the *Columbus Medical Journal*, by Dr. Ikrit, of Ohio. Dr. Coltman, Sr., read an article on the "Treatment of Unfavoroble Symptoms Developed during Anæsthesia," by Dr. Smith, of Baltimore. Dr. Carrell stated, in producing anæsthesia he first used chloroform to quiet the patient, and after the stage of excitement was over employed ether. He had found it much more satisfactory to both patient and physician. The sickness of the stomach, which is almost always present, was by this method always avoided. He had never seen any unfavorable results from this method. Dr. Doughty said he had employed this method in a

great number of cases during the last few years, and was highly pleased with the results. Dr. Cooper said he used as an anæsthetic three parts of chloroform and four parts of ether, and had never seen any unfavorable results from the administration. The crowding of anæsthetics, as often seen in our college and hospital clinics, he denounced as unscientific and brutal. If a moderate allowance of atmospheric air was allowed the patient, the struggling, fighting and almost fatal syncope, which results from the crowding of the anæsthetic, would not be produced and exhibited to the world, and their students would be better instructed on this point than they now are.

The President heartily concurred in what Dr. Cooper said, and thought the instructors of the coming medical men should teach humanity, and not brutality.

Dr. Carrell related that he had seen Prof. Wm. Pancoast, at the Blockley Clinic several years ago, operate upon a little girl for strabismus without the use of anæsthesia. The little girl stood the pain heroically, and when he was through the girl broke down and sobbed bitterly. The kind-hearted professor took the child in his arms, and comforted her like a good father.

This little spontaneous act did more in a humane way than any one ever dreamed of. It showed the true greatness of the man. It would be well if we had more such surgeons.

While it is the surgeon's duty to not shrink from giving the patient pain if necessary, still it is brutal for him to give unnecessary pain.

An Unusual Accident.

An amusing story about a local doctor was told a short time since, for the accuracy of which a contemporary is responsible. A hurried ring at the door-bell after midnight brought the doctor quickly to the window, which he threw up to inquire the cause of the hasty appeal to his monitor, and leaning forward, he fell through the window on to the pavement beneath. The servant girl who had run with the message, on seeing the sudden appearance of the white-clad form, fled with fright, shrieking "A ghost! a ghost!" To make matters worse, an untoward addition to the scene was presented by the doctor's wife, who, finding that her husband had disappeared in this unexpected manner, and hearing the voice, hastened into the street to his help. The wind blew the door to as soon as she got through it, and, in a condition of anything but full dress, the anxious wife came to the rescue of the unfortunate husband, whose knee-cap had been broken by the fall.

The Illinois Dram-Shop Act.

The Dram-shop Act in Illinois requires any persons retailing liquors to file a bond for $3,000 as security for obedience to the other provisions of the law; and a recent case in that State turned on the point whether druggists who had permits from city or village authorities to sell intoxicating liquors for medicinal, chemical, and sacramental purposes, were obliged to give such a bond. It was decided that they did not come within the intent of the law, and need not file a bond.

Recovery from a Cobra Bite.

It is not often that a person who has been bitten by a cobra lives to tell the tale. An Allahabad paper, however, gives such an instance. Very recently, it appears, while staying at Kangra, an officer of the 1st Goorkhas was bitten by a cobra in the hand. With great fortitude, Mr. R. seized his gun and blew off the finger which had been bitten; nevertheless, when medical assistance arrived, he was almost insensible, and it was only by keeping him walking about all night, and administering large doses of brandy and ammonia, that he was pulled through.

Discovery of an Ancient Crematory.

During the progress of some excavations in England recently, a crematorium, or cremation furnace, in a good state of preservation, was unearthed. Near the mouth was a large quantity of charcoal, and underneath a sarcophagus. Within the latter were found ten urns of various shapes and sizes, provided with saucer-shaped covers, and all containing ashes or partly-consumed bones. The discovery is one of great interest to antiquaries, and is remarkable from the fact of the crematorium being within the limits of the old Roman city, on a portion of the site of which London now stands.

School of Pharmacy for Women.

The School of Pharmacy for Women in Louisville, Ky., is the only school of the kind in this country. We understand that it is conservative in its tendencies and thorough in its course of instruction. At the recent commencement, held July 1, 1884, diplomas were conferred upon three women. Dr. D. W. Yandell delivered the address of the evening.

Items.

—One of the Astors has given the Cancer Hospital of New York two hundred thousand dollars.

—The Garfield Memorial Hospital, Washington, D. C., opened on June 18 for the reception of patients.

—The Health Exhibition in London is a decided success. Over 50,000 visitors are present on some days.

—Untold wealth awaits the patent medicine man that will invent an ointment that will cure the itch—for office.

—A druggist who has opened a new store in Oshkosh, advertises "Arnica, sticking-plaster, splints, bandages, and other base ball goods."

—There has been a marked decline in the number of medical students in Great Britain since 1881. In 1881, 2,171 were recorded, and in 1883, 1,783.

—On the recommendation of Dr. Woolsey Johnson, Yeng Tis Hing, a Chinaman, was recently registered as a practising physician at the Board of Health, New York city.

—The painful burns produced by nitric acid may, according to a writer in the *Chemical News*,

be successfully treated by a dilute solution of sulphurous acid applied instantaneously.

—"John," asked a doctor of the apothecary's boy, "did Mrs. Green get the medicine I ordered?" "I guess so," replied John, "for I saw crape on the door-knob this morning."

—What is called swamp fever has killed off 5,000 of the 15,000 negro laborers on the Panama Canal in the last three months. Some of the laborers are Italians, and they do not suffer nearly so much.

—The French method of administering castor oil to children is to pour the oil into a pan over a moderate fire, break an egg into it, and stir up; when it is done, flavor with a little salt or sugar, or currant jelly.

—In the *Glasgow Medical Journal*, June, 1884, Dr. J. S. Muir relates a curious instance of abnormal development of adventitious fingers and toes, as illustrating the influence of heredity in five consecutive generations.

—A Philadelphia man compels his daughter to eat onions every night for supper, and thus assures himself that he can shut the house at ten o'clock without locking in a strange young man.—*Burlington Free Press.*

—The so-called "serpent's eggs" of the toy-shops contain, says Dr. George Hay (*Medical Times*) from one to three-tenths of a grain of sulphocyanogen, quite enough to kill a child if he should happen to swallow it.

—An Italian hospital has been opened in London, and we learn from the *Gazetta degli Ospitali* that persons from all nationalities will be admitted, as well as of all religions, and all shades of political opinion.

—Senator Edmunds was particularly cordial towards the members of the American Medical Association whom he met at Washington, "because," say the graceless gossips, "he owns the biggest tombstone quarry in Vermont."

—"Why, Cousin Charlie, what are you doing here? I suppose I must call you doctor now; and how are the patients, by the way?"

"I don't know how they are by the way. I know none of them ever get as far as my office."

—An Oshkosh girl made her lover a birthday present of a bottle of "Benson's Boil-Banisher." He wrote her thanking her for the gift, but at the same time observing that he thought she lacked those spirituelle traits of character essential to his happiness.

—The Illinois State Board of Health is now engaged in revising the Register of Physicians, preparatory to publication. Any changes or corrections should be promptly sent to the secretary. Lists of the Officers of the medical societies in the State are also requested.

—Ten years ago a penniless man, with a peculiarly-shaped head, made a bargain with a London professor of anatomy by which the latter was to have the head on payment of the man's funeral expenses. Meanwhile the man became wealthy, and when he died the other day his friends tried to avoid fulfilling the contract. But the professor insisted, and the matter is to be brought before the law courts. Pending the decision, the defunct gentleman has been buried with his head on his shoulders.

—It is reported that Dr. Carter, Acting Principal of the Grant Medical College at Bombay, has found the cholera bacilli in the perfectly fresh dejecta of cholera patients. Dr. Weir, of Bombay, has found the same bacilli in the well water drank by cholera patients.

—Our sanitary representatives abroad this summer will include Dr. Alfred L. Carroll, the Secretary of the Board of Health of the State of New York, and Dr. Woolsey Johnson, one of the Commissioners of the Health Department of the city of New York.

—The following testimonial of a certain patent medicine speaks for itself: "Dear Sir—Two months ago my wife could scarcely speak. She has taken two bottles of your 'Life Renewer,' and now she can't speak at all. Please send me two more bottles. I wouldn't be without it."

—In the *American Journal of Obstetrics* for May, Dr. Baer warns the profession against regarding metrorrhagia at or just after the change of life as one of the freaks of the menopause, since cancers are found most frequently at that age, and an early diagnosis is necessary for surgical interference.

—The Minister of Public Instruction at Berlin has resolved upon a foundation of a professorship of hygiene in the Berlin University; and to this there will be attached a Hygienic Institute, under the direction of Geheimrath Robert Koch. No such institute has been founded hitherto in any of the Prussian universities.

—Dr. Fordyce Barker is reported to have said that for two years he has directed his nurses never to give a vaginal injection, unless especially ordered, in the puerperal state. Experience has taught him that patients did better than when antiseptic vaginal injections were used in a routine manner.

—The late Samuel W. Swett, of Massachusetts, left in his will a bequest of $50,000 for the Massachusetts General Hospital, to establish a convalescent department; $10,000 to the Children's Hospital of Boston; $10,000 to the New England Hospital for Women and Children; $20,000 for the Medical Department of Harvard College.

—Prof. James Law has made an elaborate report upon the disease which appeared last winter and spring among the cattle in Kansas and Illinois. He concludes that the animals suffered from dry gangrene, the result of eating ergoted hay and corn. Prof. Law's report contains a valuable review of the subject of ergotism in cattle.

OBITUARY NOTICES.

ELLEN WIRT O'NEAL,

Daughter of the late Henry Wirt, of Hanover, and wife of Dr. J. W. C. O'Neal, died of consumption of the lungs, at the residence of her husband, in Gettysburg, July 10, 1884. Born March 20, 1825. Buried in Mt. Olivet Cemetery, Hanover, Pa.

RECURRENT IRITIS, AND ITS RELATIONS TO CHOROIDAL DISEASE.*

BY S. D. RISLEY, A. M., M. D.,

Of Philadelphia,

Ophthalmic Surgeon, Hospital University of Pennsylvania.

The general features of iritis are so well understood that I shall not delay you in order to portray its usual manifestations; but enter at once upon the study of a small group of cases which shall serve me to illustrate the subsequent history of many eyes, once the subject of acute iritis.

The cases are selected, not because they present unusual symptoms or a novel history, but rather because they furnish clear-cut examples of a frequently-occurring form of disease; and I believe throw some light on the pathogeny of chronic iritis. They furthermore illustrate the serious importance of the disease, and the value of certain methods of treatment.

No form of eye disease numbers a larger percentage of blind people among its victims than those insidious, but none the less destructive processes which follow in the train of the acute plastic inflammations of the iris. It has long been observed that eyes, once the subject of this disease, are liable to progressive deterioration of vision, and often suffer acute relapses of the iritic inflammation. This liability to recurrence seemed to depend upon the presence of attachments between the pupillary margin of the iris and the anterior capsule of the lens, since it was observed that cases which recovered, having escaped the formation of posterior synechia, but rarely showed such tendency.

Von Graefe, in 1856 (*Archiv. f. Ophth.*, Bd. ii., Abt. 2, S. 202), published his important communication on iridectomy as a means of treating chronic iritis and irido-choroiditis, in which he asserts "*that the principal cause of recurrence of iritis is the existence of synechia, especially when broad and inextensible.*" Again: "*that the exclusion of the pupil is the point from which the further complications proceed, especially chronic choroiditis.*"

The method of treating acute iritis by mydriatics, at that time insisted upon by him, had for its principal motive the prevention of adhesions of the iris to the lens capsule, and up to the present time is the universally accepted treatment—the baneful influence, which he ascribed to the existence of synechia, seemed so thoroughly in harmony with the clinical features of chronic iritis, that for many years its entire correctness was accepted without a question.

Schweigger, however (Handbook of Ophthalmology, American Edition, pp. 335, Philadelphia, 1878), in commenting on relapsing iritis, employed the following language: "Such patients are for an indeterminate length of time, at intervals of a month or longer, attacked more or less severely with iritis. It is not strange that such persons generally have a number of iritic adhesions; and still this fact is the only ground upon which is based the generally-accepted assertion that these adhesions are the cause of the relapses." In substantiation of this statement he cites a fact within the range of experience, of all

*Read before the Philadelphia County Medical Society.

ophthalmologists certainly, that many persons, notwithstanding the presence of numerous synechiæ, do not suffer from relapsing iritis, and that, on the other hand, other cases do thus suffer, who have been properly treated from the beginning with atropine, in which no synechia remains.

F. Schnabel (Knapp's Archiv., Oph. and Otol., vol. v.,) has also called in question the truth of Graefe's first proposition, in an elaborate paper on the "Accompanying and Consecutive Diseases of Iritis."

Experience, however, has established upon so firm a foundation the value of the early employment of mydriatics, that we should accept only after the closest scrutiny, any report which would change our notions regarding the hurtfulness of iritic adhesions. It is, nevertheless, important that our eyes should not be closed to other conditions which may stand in a causative relation to recurrent iritis. Any doctrine accepted without question antagonizes further progress.

One object in presenting this paper is to set forth the probability *that too much importance has in some cases at least been given to the existing posterior synechia; since the plastic iritis resulting in their formation is itself often consecutive, and the subsequent eye history was probably but a continuance of the primary disease, the recurring attacks of acute iritic inflammation being only the extension forward of acute exacerbations primarily affecting the structures posterior to the iris, most probably the ciliary body and choroid.*

The following case will illustrate the truth of this proposition:

Case 1. Mrs. H., æt. 63, in good health, although from gouty ancestry, consulted me in April, 1879, for failing sight and inability to use her eyes for near work without pain: $V=\frac{20}{XL}$ in each eye. A weak concave cylinder was very positively selected with its axis at 180°, but no smaller letters could be seen. She complained of a fine web or veil before her eyes, dotted with numerous fine dark points; externally the eyes appeared normal except some enlargement of the anterior perforating vessel; the field was perfect and no increase of tension. The ophthalmoscope revealed only a hazy view of the eye-ground. The nerve was normal in color, and there was no derangement of the central retinal circulation; the visible choroid showed no change. The cornea and lens were transparent, but the anterior part of the vitreous body was hazy, and a magnifying-glass showed innumerable fine dark points as viewed by transmitted light. No web could be made out, and the dust-like particles were almost fixed. The condition of both eyes was similar.

There was no marked change after four months, during which time she had been quite unable to use her eyes. The following August, after a drive in the park, facing the western sun on a hot afternoon, she returned home with much discomfort in O. D., which during the night ripened into severe pain, which prevented sleep. The following morning, September 1, the eye was red, painful, and extremely sensitive to light. September 2, the eye was some better, and she ventured out-of-doors, the day being cloudy, and came to the office. There was still marked ciliary injection, ball tender to the touch in the ciliary region—T *n*—V diminished, and mydriasis revealed a broad synechia, attaching the lower pupillary margin to the capsule. She proved remarkably susceptible to all the mydriatics, so that I was compelled to use them with great caution to prevent serious constitutional poisoning. The eye rapidly regained its former condition, but the adhesion remained throughout the subsequent history of the case. Through the following autumn and winter Mrs. H. had repeated attacks of inflammation resulting in the formation of delicate synechia, but profiting by her first experience, the mydriatic was applied at the very outset, so that they were usually torn asunder, leaving a minute pigment-spot on the anterior capsule at the site of attachment. It is worthy of remark that however early in the attack the mydriatic was used, this attachment was, with a few exceptions, found present. The attacks occurred quite indifferently in either eye, often in both simultaneously, rarely more than ten or fifteen days elapsing without an out-and-out attack of inflammation, or a flushing of the ciliary region. These exacerbations were determined by various causes; *e. g.*, fatigue, a shopping expedition, any effort at near work, or a visit to the laundry or kitchen, immediately brought on pain and ciliary injection, resulting in an iritic attack if persisted in.

Under the internal administration of guaiacum and iodide of potassium, and the free use of the Bedford water, the attacks gradually grew less frequent and severe. 1880 was passed with only a few exacerbations, but she purchased the immunity from attack by the most assiduous care, n the avoidance of those influences which experience had taught her to dread. The balls, however, remained tender, and her vision fluctuated about $\frac{20}{XL}$, sometimes much less than this, at other

times somewhat better: on one occasion with correcting glass it was noted at $V=\frac{20}{XXV}$ in each.

In October, 1881, while sitting in church, she had marked photopsies, which were followed in a few hours by an usually severe onset of binocular iritis, which resulted in firm bands of adhesion in both eyes, notwithstanding the employment of local depletion and of atropia as vigorously as she could bear it. The eye once more lapsed into its former condition, with an additional adhesion in O. D., and a firm band in O. S. There was after this attack a marked increase in the haziness of the vitreous humor. Her former experience was now repeated. There were frequent recurrences of the iritic trouble, so that she lived in constant dread, and was greatly discouraged. Various therapeutic measures were adopted, only to be relinquished as of no avail. Iridectomy was now suggested as a probable means of permanently removing the tendency to recurrence. Sulphate of eserine had been used at different times, but only with the result of adding acute periorbital neuralgia to her present distress.

At the time I chanced to be interested in a series of clinical observations at University Hospital, on the effect of this drug over the nutrition of eyes lost by past injury or former inflammation, but now subject to subacute exacerbations and setting up sympathetic irritability of the fellow-eye. I had noticed that while solutions not stronger than 1 gr. or 2 gr. to the f. ℥i., would cause great pain and thus prevent its use, weaker solutions could be used without difficulty, and with the effect of rapidly relieving the redness of the chronically inflamed eye, and with it the irritability of its fellow.

A very striking result had been gained in a case then and still under observation. A young woman, at work in a carpet mill, came to the clinic, having been advised to have her left eye removed, to which she strenuously objected. There was well-marked sympathetic irritation, depending upon the irritable and blind left eye. The cornea of O. S. was opaque, still vascular and becoming staphylomatous at the centre, where was an adherent circatrix at the site of a perforating ulcer occurring in childhood. The eye was painful T +, and the sunlight was very painful to the right eye. She could not come into the hospital for immediate enucleation, and was very loth to submit to the operation at all; so she received a solution of sulphate of eserine, gr. $\frac{1}{8}$ to f. ℥j., to be used in the blind eye three times in the twenty-four hours, and instructions to report daily. All the symptoms rapidly subsided. The drops were used for many weeks, and although nearly two years have elapsed, she has had no serious return of the symptoms, notwithstanding the presence, on one occasion, of a small foreign body in the centre of the former corneal staphyloma, which had been allowed to remain many days.

Without room for question, the nutrition of this eye had been greatly improved under the use of the eserine. With this and other examples in mind, Mrs. H. was directed an eserine solution, .002 gm., 10 cc. to be used twice daily. In a short time after each instillation, she had a throbbing in her eyeballs and a sensation which she described as a starting forward of the eyeball, which then appeared to recede to their proper bed. There was also a slight twitching of the lips but no pain. A month later $V=\frac{20}{XX}$ with her correcting glasses in each eye. She had not been even threatened by her old enemy, and was already gaining confidence in the use of her eyes at near work. Four months later, after a long and fatiguing railroad journey, she had a mild attack in Cincinnati, but she had not neglected her homatropin solution, which, through her long trial, she had used with the earliest symptoms of an attack. This was freely instilled, and in twenty-four hours the eyes were once more quiet, and she returned to the eserine. After a lapse of two years there has been no recurrence, notwithstanding the existence of firm inextensible synechia in both eyes. The vitreous cleared up so that no trace of the former trouble could be detected. The choroidal margin at the optic nerve showed some increased pigment absorption, but no other change was noted. The ant. perf. ves. also assumed their normal condition.

I am convinced that had we the opportunity more frequently to study carefully iritic eyes before the onset of the acute and painful trouble, we should find the attack had been preceded by an interval of dim or weak sight, with disease of the choroid or retina, or both. In the case of Mrs. H., I had the opportunity to observe, first, the haziness of the vitreous body, and to follow subsequently the painful history of relapsing iritis extending over more than three years. These attacks were invariably preceded and accompanied by increased dimness of sight, due to increased opacity of the vitreous humor, as I had repeated occasion to witness. I did not hesitate to diagnosticate disease of the ciliary region of the choroid tract, notwithstanding the fact that I could discover no change in the choroid as far forward as I could

study it with the ophthalmoscope. I was, however, borne out in this by the fact of the ciliary tenderness which persisted throughout, by the dilatation of the anterior perforating vessels, and by the material poured out at each exacerbation into the vitreous. This opinion was strengthened furthermore by the inability to use the eyes at a near point.

The opinion that iritis is often secondary to choroiditis or cyclitis receives confirmation in the history of the following case:

Case 1. W. F., æt. 40 years, engineer on coastwise steamer, came to eye clinic of the University Hospital in April, 1878, with commencing iritis. A month before V. in O. D. had failed, and he had a floating web before it. The iris was discolored and he was suffering from great pain and dread of light. The pupil, however, dilated large medium under atropine, and the vitreous was filled with large grayish webs and black masses, which floated freely about with the movements of the eye. V. O. D. counts fingers. In O. S. $\frac{20}{XL}$. He gave a clear syphilitic history, and was just recovering from mucous patches in the mouth. He was admitted to the wards of the hospital, and after a tedious treatment finally recovered without post. syn. and V = $\frac{20}{C}$.

During his residence in the hospital, he complained of failing V. in O. S.—V=$\frac{20}{LXIV}$—veins of ret. large and tortuous, and the retina hazy throughout. Three days later V. had sunk to $\frac{20}{LXXX}$, and the vitreous was filled with numerous floating opacities.

Under mercurial inunctions these rapidly cleared up, and he was discharged June 20, with O. D. V. $\frac{20}{LXIV}$ O. S. $\frac{20}{XXX}$. The following December he returned with failing V—dread of light and cil. redness. He remained under observation for over two years, in the meantime having repeated attacks of iritis. He carried with him a sol. of atrop. sulph., which was applied as soon as he noticed any aggravation of his eye trouble, and thus prevented formation of adhesions to the capsule. He had many more relapses of dim sight on three separate occasions, affecting the left eye also, which, however, never resulted in iritis. The patient was an intelligent man, and soon learned to treat himself with much skill. He had learned that, unmolested, his attacks of increased impairment of vision in a few days resulted in attacks of iritis. He therefore did not wait for the attack, but began treatment at once. He would swallow a saline cathartic, instil his atropine solution, don his smoked glasses, give up all attempt at near work, and quietly await results. If the attack threatened notwithstanding these measures, he applied leeches, which he carried with him while at sea as a precautionary measure. The attacks in the left eye were ushered in by flashes of light, and either a hazy retina or cloudy vitreous, soon to be followed by floating opacities.

In this case there can be no question but that the recurring iritic attacks were consequent upon increase of the choroidal disease. Furthermore, the recurring attacks of iritis, both in Case 1 and Case 2, demonstrate the truth that relapses of iritis are not necessarily dependent upon the presence of synechia, and lend support to the assertion of Schnabel (*loc. cit.*), that "experience has taught me that eyes possessed of synechia are no more liable to relapses of iritis than those which have passed through an iritis without retaining any synechia."

I have been greatly interested in the retinal condition present in irido-choroiditis. In Case 2 the attacks in the left eye were attended with all the necessary manifestations for a retinitis. It is improbable that any serious disease of the choroidea can exist without leading to a pathological condition of the retina, and doubtless the reverse may be true. But it must be remembered that any study of the eye-ground in iritis presents great difficulties, because of the almost constant presence of semi-opaque media, and the great dread of light experienced by the patient. In my own experience, I have been more frequently thwarted than successful in the attempt to do so. When extensive synechiæ are formed, there is also very frequently a web-like opacity of the anterior capsule, which precludes any satisfactory inspection of the tissues beyond it.

(*To be continued.*)

MEDICAL EDUCATION AND STATE LICENSE.

BY ROMAINE J. CURTISS, M. D.,

Of Joliet, Ill.

The reader of medical journals during the last few months must be impressed with the general complaint that the profession is overcrowded, and must have also taken note of a general remedy that has been suggested, which is to separate the teaching power and the licensing power, or to permit teachers to educate, but to take away

their power to grant diplomas which the state is bound to respect.

The structure of this complaint is built up of certain factors, and so is the structure of the proposed remedy; both of which factor classes I will enumerate, and venture an attempt to analyze.

THE COMPLAINT.

1. The profession is said to be overcrowded because there are upwards of 80,000 doctors in the United States—a proportion of one to six hundred of the population. The proportion is alleged to be incompatible with the professional activities, or "practice," by which a doctor must make his living, and support his family, and lay up money for a rainy day, and for his children.

2. The overcrowding of the doctors is said to be caused by the too numerous medical colleges, which entice, partially educate, and grant diplomas to young men far too numerous to mention. The standard of medical education is declared to be too very, very low, and that it must be raised, not by educating a greater number, but a less number to a higher standard; and to do this, personal liberty in education, both for student and teacher, must be taken away.

THE REMEDY.

1. The factors of the proposed remedy are to lessen the number of medical colleges by legal proscription, of course; taking away their charters very likely, and refusing to charter more. When the number of colleges in the United States is reduced to five or six, then the faculties are to be appointed by the political machine, and the term of study of a limited number of students is to be increased to five or ten years, during which time they are to be crammed with special questions and answers in "medicine" and the allied sciences; and when they are considered to be sufficiently crammed with these special facts and fancies, they are to be examined by a board appointed by the political machine, and if found qualified they are to be licensed by the state to practice medicine.

2. Some of the more zealous of the medical prohibitionists suggest that politics should not only control medical education in colleges which are run by individual or corporate enterprise, but that the government should start a medical college, or should take charge of medical education entirely, just as the government does the post-offices. These enthusiasts, who are so afraid of private enterprise, say that the only medical college, or at least the head-centre college, should be in Washington, and that the faculty ought be appointed as postmasters are—perhaps under civil service rules—and should the exigencies of the service require, then perhaps a college or sub-college might be established in St. Louis, and perhaps other cities.

COMMENTS.

I will offer comments on the preceding propositions, under the heads of (*a*) Causes of the Alleged Over-crowding of Doctors; (*b*) The Nature and Quality of Education; and (*c*) The Relation of Government to Individual Rights; and will try to show the fallacies of the propositions, and the true relations of medical education and the doctors to each other and to politics; and take a little look for the true sources of relief, should it really be learned and experienced that doctors are too many and too ignorant.

(*a*) Are the doctors too numerous, too poorly educated, and if so, what is the cause?

The principal evidence, so far as brought forward, of too many and too ignorant doctors, is numerical. The proportionate ratio of the physicians to the total population is given, and the assertion made that the number is too great. Obviously there is no proof of the proposition in these figures. The figures lie in the light of known professional success, for the doctors, with the exception of the clergy, are the longest-lived class, and I have never heard of the righteous seed of Æsculapius either begging or stealing bread. Nay, if the doctors will refuse to treat patients without pay, in dispensaries and private practice; or even withhold the chromo to entice the patient, in addition to the gratuitous treatment, then, perhaps, the public would think doctors not too numerous, and those philanthropists, as a class, might outlive the clergy.

The only evidence of the overcrowding of a working, or business, or professional class, which is at all approaching proof, must be that a certain proportion are unable to make a living by their calling, or physiological activities in this special line, whatever it may be.

Now, there is no general evidence or proof from this source which proves the proposition. Like all other callings, the profession has members who fail to adapt themselves to the character of activities required in order to be successful in getting a living, and are obliged to leave it for something else. There are thousands of people on earth who can not adapt themselves to anything, and are supported instead of being killed by the community; yet the population, at large, of the earth has not put in a complaint against the procreation of the species—at least since the day and labors of Malthus.

The cry of professional over-crowding is simply a professional trade-union howl. It is the regard for self, with the other fellow left out. It embraces all that is selfish, with nothing that is altruistic. It is conservative in the direction of self-preservation, but the element of duty, which gives the other man liberty to make a living also is absent.

The social law (which ought to be adopted by the "Code") is that all men have equal rights to exercise their gifts and faculties in pursuit of a living and happiness; and it is a corollary, that while all men have this privilege, they must all be subject to the other side of the proposition, which is that they must not interfere with each other's rights. To specialize in a medico-ethical direction, the conclusion is that no body, or organization of medical men, have any ethical right to declare that the profession is overcrowded, unless the proof can be shown, nor to take any steps to prevent by law the entrance of any person upon the study and practice of medicine, when other things are equal. The social law of equal rights and equal ethical duties in medicine will not allow any corporate sect or body of medical gentlemen to prescribe anything different for medical students than what the same gentlemen enjoyed, or to which they were subjected. A higher medical education can't be brought about in this way. The demand must come from natural competition in professional life, under the law that the fittest shall survive and propagate his kind.

But there is a feature of ethics having most important relations to the over-crowding of doctors, which comes within the range of legal control, and should engage the attention of medical gentlemen who are so willing to devote their services to the welfare as well as the "dignity of the profession." I allude to the charity (?) work of doctors in hospitals, dispensaries, and private practice. This alleged charity is the chief stumbling-block to professional success and to professional dignity. This charity represents millions of money every year, and is all money that should be paid to doctors. It is money that should be paid to the great over-crowded crowd who rush in and beg for a chance to do the work without pay and without price. Charity, in a civilized community, should always be at the expense of the corporation, and should not be individual, especially when the gift represents money that could be earned by another. When a doctor consents to attend a poor patient for nothing, or a public pauper for nothing, he is robbing the profession, as a class, of the cash value of his services. It is such work as this that makes the profession overcrowded. It is this kind of work which is, above all else, unethical in medical practice; for the money is taken indirectly from the pockets of doctors, and is a contribution of the profession to the community at large, which the profession is not able, especially in its over-crowded state, to contribute; and it must be told that the community do not rob the doctors of this money, but a few doctors, who have "a higher medical education," are the criminals before the Court of Ethics.

This feature of medical practice is so heavy with ethical outrage toward the medical profession, and of injustice to the public or governments, that it is difficult enough to say so little about it. I will leave the subject to the prayerful consideration of every doctor who feels a lively interest in his brother's education and prosperity, and will proceed to consider other features of the question.

The relation of medical colleges to the number of doctors, whether large or small, is certainly not as stated in the "complaint" or the "remedy." The fundamental law which determines a man's business or calling, as well as determines the production and consumption of all material, is called the law of supply and demand. The colleges are a means between supply and demand, and are themselves demanded, or they would not be supplied. Among the more immediate antecedents causing the supply of students, is to the fact that doctors instigate young men to become students in medicine. The young man gets his ambition and resolution in this direction from the example—the professional excellence, grandeur, education, dignity, and wealth—of the man who becomes his "preceptor" and not by gazing on the outside walls of a medical college. The young man may be a son or neighbor, or only the hostler and office-boy of the doctor. At any rate, the fact cannot be disputed, and every doctor's history will show it, more or less, that such are the initial circumstances, or conditions, or forces, which entered him at the wicket-gate, at the right beginning of the pilgrimage—provided he did not climb over the wall 'way down the walk, and register as a medical pretender.

Now, there being about 80,000 doctors in the United States, with strong tendencies to become preceptors, it would be interesting to know how many of them have sons, or office-boys, or neighbors, or prospective sons-in-law, to whom they are, even at the present time, the "preceptors."

During the past fifteen years, there has been a triennial crop of from five to fifteen thousand medical students. To accommodate these students, the colleges have rapidly increased. No one need deny that the people who are the proprietors of the colleges are beneficiaries, directly or indirectly. There is great honor in being a medical "professor," and acting as hero to a full clinic and dispensary, and consulting surgeon to a hospital; so that the demand for colleges and teachers has never suffered for lack of this material, though there may have been some deprivation in places, of other *material*. As is well known, the colleges in larger cities have been overcrowded with students. It is not unusual that the class of such colleges has numbered every winter from four to seven hundred. Colleges in smaller towns "have had no reason to complain," and it may be true that in most towns of the United States with a population of 100,000 and over, the town has ambitions and pretensions of being a centre for railroads, manufactures, elevators, and boards of trade, as well as a "medical centre."

Obviously, then, if the colleges are not the initial cause of the large number of students, the proposed remedy of lessening the number by law or other compulsion, say the gentle pressure of ethics, will not lessen the number of students, who will simply overcrowd the colleges which are elected to survive. So long as men, whether in the ratio of one to six hundred or one to three hundred, can make a living in the practice of medicine, they will get as good a medical education as they must have in order to compete successfully, and be happy as living members of the most foolishly charitable and most foolishly uncharitable (in different directions) of any class of people on earth.

Looking at things as they really are, then, the candid thinker must reach the conclusion that the charge of over-crowding is untrue, and is founded upon the selfishness of the persons who make the charge; and this conclusion is further warranted by the proposed remedy, which seeks to strangle the young brood by imposing an impossible standard of education, destroying educational means, and turning the whole matter of education, and right to be medically educated, and to practice medicine, over to politics. Verily, such a proposition has not been promulgated since the doctrines of Malthus were made public.

But, looking further, we may find very readily what are the causes of the demand for doctors, which it may be admitted is rather fully supplied. The cause is the lack of sanitation. People are unable, and unwilling, to prevent disease. They want the disease "cured" which afflicts them; they do not want it prevented. The curing of these diseases, and the hurts which afflict the people of the United States, keeps 80,000 doctors "quite busy;" at least, it is the lack of sanitary precautions, and the alleged curing of the diseases of 53,000,000 people, which creates the demand for doctors, and which supply is furnished by young men who become students of preceptors, and then students of colleges.

The ethics of medical science (every science has an ethical side) is, it must be plain to every thinking person, to promote the knowledge of the prevention of disease among the people—professional people, as well as the laity. There is not much medical ethics in a body of men who call vainly for a higher standard of education in curing diseases where there are no cures known, and say too little about what is known of prevention, and then "cure" people in great part for nothing, and quarrel about the great number of men among whom the spoils of the paying patients must be be divided. From such a class of men, one might expect, would originate the impossible, and deplorable, and disgraceful method of turning medical qualification over to the political machine, with the object of diminishing professional competition.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL,

BY CHARLES K. MILLS, M. D.,

Neurologist to the Hospital, and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by WILLIAM H. MORRISON, M. D.

Tumor of the Brain—Autopsy.

GENTLEMEN: I have here the specimens from a case on which I made an autopsy this morning. It was a case of multiple brain tumor, which I had seen in consultation. From the details of this case you can obtain the essential points in the diagnosis of brain tumors.

The patient was an Irishman, 19 years of age, who had been in this country only one year. He was perfectly healthy before he left Ireland, and he remained healthy for eight or nine months after coming to America. Three or four months ago he began to suffer with headaches. At first they came and went, but soon lasted a longer time. He also had, although not to a marked degree, attacks of vertigo. About six or seven weeks ago, while at his work, he was suddenly attacked with

partial loss of power in the right hand and arm, and also complained of a little weakness in the leg. A little drawing of the face was noticed. He consulted a physician, was prescribed for, and the paresis disappeared, and he went to work. During this time he was working as a hostler in a street-car stable. Three weeks ago he was kicked on the side of the face by a mule. After this, the headaches became much worse. There was some loss of power of the right side, but no actual paralysis. He continued to work until two weeks since, when he was compelled to go home and take to his bed. I saw him first about a week ago.

He was at that time in a dull condition, although not comatose. He was on his back, entirely paralyzed in his right arm, nearly so in his right leg, the face drawn slightly to the left. There was also ptosis on the right side, and doubtful strabismus of the left eye; that is, it could scarcely be determined whether or not a squint was present. I examined him very carefully for sensation, and although he could give no response in words, he could indicate where he felt pain. This examination showed that there was loss of sensation, although not absolute, on the right side of the face. As soon as the middle line was passed and the instrument was applied on the left side of the face, he began to respond, and he evidently suffered pain. He undoubtedly suffered severe pain in the right side, and he so indicated as long as he could indicate anything. He had both anæsthesia and pain. This is not an impossibility. With depression of sensation, a condition of this kind may exist, just as there may be severe pain in the trigeminal nerve, as in anæsthesia dolorosa, with loss of sensation to certain tests. He had at times slight twitching of the right hand. During the last week of his life, he lost control of the bowels and bladder. A little irregularity of breathing which approached the Cheyne-Stokes breathing was observed, although there was no absolute descent and ascent in the respirations, simply a little irregularity approaching this type before he sank into a stertorous condition. He had complained somewhat of his eyes, but no ophthalmoscopic examination was made. He sank into a stuporous condition, and died yesterday.

My diagnosis was a tumor or an abscess, more probably the former. I thought that the tumor was probably due to syphilis. There was no known history of syphilis. It however seemed to me that no other diagnosis could be made.

The post-mortem examination was made this morning, and here is the result: Here is a mass —small, it is true—but unquestionably a tumor of some kind. Here is a much smaller mass, not much larger than a pea, from the inferior angle of the right lobe of the cerebellum. In addition to these masses, some meningitis was present at the base of the brain, with a little effusion. There was a little streaking over the fissures of the surface of the brain. The pia mater was injected, but about as much on one side as on the other.

This larger growth was almost exactly in the ascending frontal convolution, at the junction of its middle and upper thirds. A portion of the mass (perhaps a third) was on the convexity of this convolution, while the rest was in the fissure of Rolando. The growth did not involve the ascending parietal convolution. There was no pus, as often occurs in cases of some standing, nor any breaking down of tissue. It was simply a case of localized tumor, involving the motor region of the brain. It was absolutely localized in the ascending frontal convolution, and only affected the ascending parietal, if at all, by pressure.

A slight discussion of this case may be profitable. This is a case in which, if the trouble had been recognized early, the man could, perhaps, have been cured; that is, if any case of cerebral syphilis can be cured, and undoubtedly some can be. If this had been recognized several weeks ago, the fatal result might have been prevented. When he came under the care of his attending physician, two weeks ago, the disease had advanced too far to be relieved. This illustrates the importance of an early recognition of troubles of this kind. I may, perhaps, be taking too much for granted; this may possibly be a tubercular growth, but I do not think so.

At the time of his attack he was living in a malarial district and had been treated for malarial trouble, without any reference to the special condition in the brain. The peculiar phenomena were not recognized.

I believe it within the bounds of possibility to have successfully removed this cortical growth by operation, if no basilar trouble had been present.

He had the symptoms which I should lay down as the typical manifestations of brain tumor, and which will enable the diagnosis to be made in the incipient stage or in any step of its progress. A tumor of the brain is nearly always a tumor of the membranes. It usually is a growth from the pia mater or the dura mater, and very commonly, when the post-mortem is made, these two membranes are found agglutinated together. Many of these tumors originate in the pia mater. Such was the case in this instance. The dura mater was not involved in the growth. It was a highly-congested condition which was most marked near the site of the growth, but it was not adherent to the pia mater.

The general symptoms of brain tumor here present were headache, vertigo, mental disturbances, hyperæsthesia, and usually choked disk. All the post-mortem appearances indicated that the man had this condition of the eyes, although we were unable to obtain an ophthalmoscopic examination before death. Hyperæsthesia is very common in cases of brain tumor, even on the side of paralysis. Vomiting, usually a symptom, was absent. The other phenomena depended on the seat of the lesion. More or less marked paralysis, and often spasm, are present when a tumor involves the motor region. In this case, spasm did not exist except as a slight monospasm. There was a history of paresis which came, disappeared after a time, and returned. This is often the history of a tumor of the convexity, which is not of large size. After a time apoplectiform attacks occur, and the condition remains permanent.

This case bears out the doctrine of localization. The localizationists, and I am inclined and have always inclined to be a localizationist so far as the functions of the brain are concerned, would account very beautifully for the paralysis of the arm by the position of the tumor pretty nearly in

the middle Rolandic region, here towards the middle of the ascending frontal convolution. According to the localizationists, this Rolandic region is divided into three elliptical regions, the upper one containing the centres for the leg, the middle one the centres for the arm, and the lower one the centres for the face, and a little anterior to the latter the speech centres are located. In this case there was no breaking down of the white matter behind the tumor. It was a beautiful instance of a strictly localized growth. The paralysis was due to this growth in the motor cortex. Inhibitionists might say that the paralysis was due to the irritation of both growths irradiated to certain regions and inhibiting motion. As a matter of fact, we know from experience that if the tumor had been in the occipital lobe, there might have been sensory phenomena, headache, vertigo, and the general phenomena of brain tumor, but there would not have been paralysis, or at least not localized paralysis. A tumor in the antero-frontal portion of the brain would have given the general symptoms of a brain growth, but not paralysis. Whatever view you may take of localization, whether you take the view that there are true volitional, psycho-motor centres, or the view that there are certain regions in which lines of force are concentrated, without question is a sort of localization.

I should say that the paralysis in the right arm and leg was due to this tumor of the convexity, and to the irritation and pressure which it exerted on the general region in its proximity. We get not only the fixed pressure, but the irradiation and the impairment of the region in proximity to the growth.

Let me say a word as to the other growth and the other phenomena. The tumor on the convexity of the brain ought not to have killed this man, or at least not so soon. I have made autopsies of cases which had lasted for a year or two, with larger growths than this. He had also a tumor in the right side of the cerebellum, in close proximity to the pons and medulla, causing some pressure, but no destruction, and very great irritation in the neighborhood of the vital regions. It undoubtedly gave rise to a local meningitis. There was, however, no destruction of tissue. There was also effusion at the base. He died more from this meningitis and effusion at the base than from the larger one. The ptosis and the trigeminal anæsthesia may be accounted for without going into minute details, by the condition at the base of the brain.

You should always be on the lookout for cases of this kind. Within the past year I have been called into case after case, where if the correct diagnosis of syphilitic disease of the brain had been made, instead of malaria, or some other trouble, the chances of the patient would have been much better. Such cases should be put on the use of iodide of potassium and mercury, ergot and bromide of potassium being given to relieve the congested condition.

In view of the history of traumatism, I may say that I carefully examined for any evidence of fracture of the base or convexity of the skull, but found none. There were no ecchymoses such as are present in some cases of concussion without fracture. I have no doubt that the growth was at the bottom of the trouble, and that if the traumatism did anything, it simply served to light up the brain trouble.

Medical Societies.

PHILADELPHIA NEUROLOGICAL SOCIETY.

A stated meeting of the society was held Monday evening, April 28, the President, Dr. S. Weir Mitchell, in the chair.

Dr. J. Hendrie Lloyd read a paper entitled

The Report of a Case of Pseudo-hypertrophic Muscular Paralysis with Bone Lesions.

Sarah C., æt. 17, was one of the first inmates of the Home for Crippled Children, after its establishment by Mrs. Innes, in the early winter of 1883. The patient presented, when first seen, an appearance of great obesity. The fat was generally distributed to the face, neck, trunk, gluteal regions, arms (partial), and legs. Some of the muscles of the forearms were slightly wasted. The appearance was one of great robustness ef health, and the accumulation of fat and general outlines of the figure were such as to suggest an over-fed, middle-aged woman, rather than a girl but half advanced in her teens. Upon closer inspection there was discoverable a strange contrast to this appearance of health. It could be readily seen then, that the patient was a complete cripple. So absolute was the loss of power that she either lay supine, or was propped with pillows in a large chair, the body spreading out, as it were, by the mere force of gravitation, and without muscular resiliency or the control of will power.

The girl was, and now is, so helpless that it is impossible for her to assume the sitting from the reclining position; she cannot turn upon her side without assistance, and it is with the greatest difficulty that as she lies upon her back she crosses one leg over the other. She retains, however, some power in her arms, especially the forearms, and although these regions are evidently wasting, they alone seem to possess what fraction of power the girl can command, and with them she can sew, crochet, and do other work requiring skill and training.

The details of her condition are briefly as follows: The muscular system presents in many places marked enlargements. These are evident especially in the deltoid, lumbar muscles, and calf. The muscles in these regions have a dense, doughy feel, and are overlain with subcutaneous fat, with which they appear so intimately connected that it is difficult to detect their exact limitations. They are very little, if at all, subject to the will, so that their passive condition and their envelope of mottled and lifeless-looking skin is very suggestive to one who handles them, of some profound pathological change.

This pathological change has been demonstrated by the microscope, and is in accord with the classical description of pseudo-hypertrophic muscular paralysis. With the aid of the little instrument of Dr. Harte, of this city, specimens of the muscular tissue were taken from the lumbar region and the calf. Dr. William E. Hughes kindly

prepared these for examination, by teasing them, as the fragments were too small for embedding and cutting. The specimen from the calf presented under the lens an interstial hyperplasia, with granular changes in the muscular fibre, and a marked loss of striation. There was not any appearance of secondary fatty change in the connective neoplasm, which may possibly be accounted for by the "teasing" process. The specimen from the lumbar region was not apparently from the muscle, but was simply adipose tissue.

The reactions to the faradic current in the deltoid and calf muscles are very feeble. The reactions with sponges on median and ulnar nerves of forearm—the muscles of which are wasting—are about normal, or, at least, much more active than in the hypertrophied muscles. So, too, in the peronei. The reactions of degeneration to the galvanic current have not as yet been sought for.

The girl was weighed some months after her admission to the Home, and after she had evidently lost much flesh, turned the scale at 124 pounds. When first admitted it required the combined strength of two men to carry her up stairs, and she, no doubt, at that time weighed considerably more. Her stature is not tall, and her age at that time not seventeen. The measurements of her limbs are at present as follows: Upper extremities, arm, right, 12½; forearm, 9; arm, left, 13; forearm, 9. Lower extremities, right thigh, 21; leg, 13¼; left thigh, 21¼; leg, 13.

These figures show an increase of bulk during the last few months. The girl's mind is fairly bright. She is something of a giggler—simpering and foolish—but her defects may be partly, at least, accounted for by lack of opportunity and education. She cannot be called a feeble-minded child. The patient's history is very obscure. Her mother "ran away with another man," as her brother explains in a letter, and she has passed her life in public institutions. This brother says he thinks she was always a cripple, but not so bad but that she could at one time walk. Her general health is excellent; she attempts to add constantly to her exuberant proportions with a vigorous appetite, and is now putting on fat. The heart and lungs are normal. She occasionally suffers pain from the spinal curvature, to which reference will be made in a moment. There is no evidence of heredity. She at one time menstruated very freely, and as often as every two weeks.

But while the appearance of the muscles is so significant, there are changes in the bones of still greater interest, and to which I desire to call your attention. These changes have occurred in the spine, and in the elbow and knee-joints. The spine is in a state of constant scoliosis, with its greater convexity to the right. One year ago, this convexity could be thrown to the left by one attendant lifting the patient by the shoulders, and another making pressure on the vertebræ. It would not remain thus, however, and was evidently uncomfortable to the girl.

The elbow-joint presents a unique appearance, which, as far as I am at present informed, has not been described in any other reported case of pseudo-hypertrophic muscular paralysis. It is exceedingly mobile, due apparently to an atrophy of the epiphyses of the bones. Thus, the joint can be bent backward at a marked angle, quite impossible when the olecranon and its opposing surface are intact. The attachments of the head of the radius and upper end of ulna are loosened, allowing a sort of wabbling and limberness in making pronation and supination. This preternatural mobility is increased by a somewhat similar condition of the head of the humerus in the glenoid cavity.

The wrist-joint, also, is not firm and staunch (depicted by Dr. Taylor). The chief defect of the knee-joints is an atrophy of the patellæ, which are not more than one-half their normal diameters.

In bringing this case to your notice, I desire especially to call your attention to the fatty phenomena and to the bone lesions. The literature of the subject presents nothing which has added much to the original description of Duchenne, supplemented by a few very thorough post-mortems—especially of Eulenberg and Cohnheim. Duchenne said that the interstitial connective tissue proliferated with the production of fibrous tissue, and that this increase was associated with fat vesicles; also that the striation was preserved, but was very faint. He does not bring into prominence the fatty changes, which seem to be secondary to the hypertrophy of the connective tissue. Other writers, apparently following Duchenne, or perhaps not seeing cases in which fatty changes are prominent (for they are rarely as marked as in our case), have not discoursed much upon the phenomena of lipomotosis. Duchenne says "the subcutaneous tissue contains very little fat." Eulenburg, however, has brought these changes prominently forward, for in his monograph—founded upon his post-mortem researches—he says there is a great increase of subcutaneous fatty tissue, "most noticeable in places where nature has provided an abundant panniculus;" and, moreover, says of the intermuscular changes that there is first a proliferation of connective tissue, which is transformed into fatty tissue. I think that our case is a striking example of this pathology.

The bone lesions in this case are interesting in view of the tendency at present to connect bone and joint changes with diseases of the central nervous system. This speculation is not a new one, for it was a suggestion of Prof. J. K. Mitchell, years ago—so he is quoted—that rheumatism may be of neurotic origin. Arthritis deformans has been recently attributed by Weber to a neurotic source, but the argument is largely from a therapeutic standpoint, viz: as the disease does not improve on anti-rheumatic treatment, and does improve on general tonic and galvanic treatment, ergo—a neurotic origin. There are undoubted bone lesions, caused by disorders of the cerebro-spinal axis, as has been shown by Prof. H. C. Wood in a recent clinical lecture. He refers to bone changes in insanity, especially dementia paralytica, in hemiplegia and locomotor ataxia. These changes are described as atrophy, hypertrophy, and inflammation. A true causative relation is shown, but we are wahting in an exact pathology as to what trophic centres, if any, are affected, and in what manner. Bone lesions in pseudo-hypertrophic muscular paralysis have not been brought into any prominence in the investigations which I have consulted, and in many cases not even referred to. Scoliosis, which ex-

ists in one case, is mentioned by some and ascribed to the weakened state of the muscles—no doubt a true explanation; but such changes as I have described in the elbow and knee appear to be unique.

As a probable explanation of these impaired bones, I am reminded of the dictum of Duchenne. It was not the belief of this great clinician that pseudo-hypertrophic muscular paralysis was at all identical with progressive muscular atrophy, or that it was of central origin. It seems probable that the case before us may be an expression of that faulty development which overtakes, in some defective births, all tissues, and that pseudo-hypertrophic muscular paralysis, associated, as it often is, with impaired brain and nerve function, may be but a form, in some cases at least, of congenital deficiency of development power.

Dr. Charles K. Mills said he had that day seen a case at the Philadelphia Polyclinic, interesting in connection with Dr. Lloyd's remarks on bone and joint lesion originating from the nervous system. The case was that of a mulatto woman who is changing to a bronze color, and in addition, the upper half of the body is affected with muscular atrophy. The joints, more particularly the smaller ones of the right hand, are swollen, rigid, and painful; the hands were in a half-closed position. She had perverted sensation in her face, loss of the sense of taste, difficulty of swallowing, and could only open her mouth half way, on account of the muscles of deglutition and mastication being affected. The case illustrated the connection between muscular degeneration and joint and other trophic affections.

Dr. N. A. Randolph read

A Note on the Behavior of Hydrobromic Acid and of Potassium Iodide in the Digestive Tract.

I venture to present before the society a brief note upon a subject not strictly neurological, but having direct bearing upon the relations entertained to the processes of digestion by two drugs, which are of interest to the neurologist.

In a series of artificial digestions, in which hydrobromic acid was present in the digestive mixture, in amount corresponding to the therapeutic dose, I have noted:

(*a*) That salivary digestion was completely suspended, whereas

(*b*) The peptonization of proteid food-stuffs was in nowise retarded, the variation from the normal, if any, being toward an acceleration of this process.

It is evident, therefore, that, other things being equal, the appropriate time for the exhibition of this drug is immediately upon the cessation of salivary digestion within the stomach, or in other words upon the first formation of free acid within that viscus.

Recent studies* have shown that the acidity of the gastric contents, found even in quite early stages of digestion, is not due to the presence of *free* acid; and the ingenious observations of Von den Velden† go far toward proving that the development of free acid within the stomach does not occur until from forty-five minutes to an hour after breakfast, and from one to two hours after dinner. These results were obtained chiefly by the use of methyanilin, violet, and tropæolin bodies, delicately responsive, by color-change, to the presence of free acid. There is little doubt in my mind that hydrochloric acid is developed in the stomach at an earlier period than that above indicated, but it seems very probable that by immediate combination with albuminoid it loses somewhat its characteristic activity. This is illustrated by an observation made in the course of this study, namely, that the addition of small amounts of potassium iodide to dilute solutions of acid albumin containing two-tenths of one per cent. of hydrochloric acid, does not result in the liberation of iodine. The addition of the same amount of the iodide to the same quantity of an aqueous solution of hydrochloric acid of the same degree of activity results in an immediate liberation of iodine.

This interesting discovery of two stages of acidity in the gastric juice has, I believe, not yet been incorporated in the text-books. It serves to reconcile the contradictory opinions so frequently found as to the value to the economy of saliva as a digestive fluid, and explains the completely diverse results obtained by such careful workers as Frerichs,* and Bidder and Schmidt.†

Besides an observance of the time-limitations just indicated, I would suggest the advisability of milk as a vehicle for the administration of hydrobromic acid. The curd thus formed is fine and flocculent, the mixture closely resembling buttermilk in taste and appearance, and in no wise suggesting medicine. I have taken as much as a tablespoonful of the dilute acid in a tumbler of milk, without any repugnance. The milk used must be raw. With this, as with most other acids, boiled milk gives tough and bulky coagula.‡

As regards the exhibition of the iodide of potassium, the rationale of its time relations is altogether different. Although this drug is distinctly alkaline, its presence in a mixture of hydrated starch and saliva certainly does not suspend the action of the amylolytic ferment, nor, so far as I can determine, materially retard it.‖ When, however, iodide is added, even in very small amount, to a mixture of artificial gastric juice and egg albumin or fibrin, the rapidity of peptone formation, as determined *by the nascent* murcuric iodide reaction,§ or by the biuret reaction and control test, is greatly diminished. This result is not due to a slight diminution in the acidity of the solution, caused by the addition of an alkaline body; for the same effect is noted when the acidity of the solution is at once again brought up to the normal degree. The pepsin is apparently but little, if at all, affected by the

‖Langley & Eves, Jour. of Physiologie, iv., p. 19, have shown that although a distinctly alkaline medium retards salivary action, the presence of a proteid body in the digestive mixture will prevent this retardation.

§Randolph; A reaction common to peptone and bile salts.—*Proc. Acad. Nat. Sci. of Phila.*, 1884.

presence of the iodide, if we may judge by the indifference of ptyalin to the drug, and by the fact that quantities of the iodide corresponding to the maximal therapeutic dose neither entirely suspend the peptic activity, nor induce greater retardation of the digestion than do much smaller quantities. A slight effect is exerted by the iodide upon the proteid food-stuffs, evidenced in an increased toughness produced in, *e. g.*, fibrin, and when the drug is abundantly present, in the acquisition by the albuminoid of a slight yellow tinge, due to staining by iodine, which is liberated by the free acid of the artificial gastric juice.

The most important factor in the delay of peptonization lies in the power possessed by potassium iodide, even in relatively minute quantity, of precipitating acid albumen in solutions which shall, after its addition, possess the normal degree of acidity of human or even canine gastric juice. The same may be said of potassium bromide, and of several other analogous compounds. The precipitation effected by the iodide is so complete that when solutions of acid albumin are thus treated and filtered, the still acid filtrate yields no trace of proteid matter. This observation, which is doubtless old, though I have as yet been unable to find it recorded, tends to show that the time at which the administration of this drug is least liable to disturb digestion is either during or immediately after the ingestion of food.

There are several sources of error in attempts at deduction from the results of artificial digestion, as ordinarily performed. Thus the continued activity of a digestive fluid is largely conditioned by the removal of the products of its action soon after their formation. This occurs in the living viscus, but not in the test tube of the experimenter. The maintenance of the normal temperature of the active stomach is, of course, readily accomplished; but the conscientious imitation of other factors in the normal digestive process implies not only a constant mechanical intermingling of food-stuff and digestive fluid, but the continued addition of small amounts of the digestive fluid itself. I have nearly perfected an apparatus which in a large degree obviates the difficulties just cited.

In it artificial salivary digestions are conducted in a thin tube of fish-bladder, closed at one end, which is, by mechanical means, kept in gentle agitation. The contents of this tube are maintained at the proper temperature by a surrounding body of warm water, which is slowly but constantly changed. For gastric digestions the animal membrane is substituted by one offering equally great surface for dialysis, but resistant to peptic action. Despite, however, the inaccuracies attending existing methods of study, the following deductions from the facts, old and new, which are here presented, appear justifiable:

1. That the earliest production of free acid within the stomach is approximately three-fourths of an hour after a meal; its appearance being still further delayed by the ingestion of food in large quantity.

2. That hydrobromic acid is liable to impede the digestion of starchy foods when administered within the interval just named; and

3. That iodide of potassium should be given at such time and in such dilution that its absorption shall be complete before the appearance of free acid within the gastric contents.

Dr. Francis Dercum said he thought the suggestion of using milk as a vehicle for hydrobromic acid, a very good one.

Dr. S. Weir Mitchell spoke of the utility of hydrobromic acid given with bromide of potassium.

Dr. E. T. Reichert referred to the paper recently written by Dr. H. C. Wood, on the "Use of Hydrobromic Acid in Epilepsy." He said it confirmed the conclusions which he had come to in a paper on the physiological action of hydrobromic acid, published some years ago. He believed that hydrobromic acid could be substituted for bromide of potassium, as it had the same physiological qualities as the bromide.

Dr. S. Weir Mitchell read a paper on

Œdema of Hysterical Hemiplegia and Unilateral Swelling in Hysteria Generally.

Dr. Charles K. Mills said he had seen similar cases to those reported by Dr. Mitchell, but had not studied them closely. In a case of hystero-epilepsy, with hemi-anæsthesia, etc., there was œdema of both limbs, but the swelling was most marked on the affected side and was chiefly below the knee. In another case recently seen at the Philadelphia Hospital, the swelling of the limb was very decided.

In some cases of hysterical paraplegia he had noticed these swellings, but had not made them a special study. He also referred to a case of hysterical contracture of the wrist with marked œdema.

Dr. Sinkler spoke of having seen a number of cases of slight temporary swellings of the limbs in hysterical women. He mentioned a case of this kind which he had seen at the Orthopædic Hospital. It was that of a woman whose hands, feet and legs would become, at times, slightly swollen; but it was temporary, as it would entirely disappear.

The Treatment of Scrofulous Pyonephrosis.

The treatment recommended by Dr. R. Clement Lucas (*Brit. Med. Jour.*, July 5, 1884,) consists in cutting down upon the kidney through the loin, draining, and disinfecting it. Afterwards, when the organ has contracted, should it remain a source of discomfort, it may, with comparatively little danger, be removed without opening the peritoneum. At the time of his report there were two cases of scrofulous kidney lying in Guy's Hospital, under his care, each with a tube in one kidney. To those unfamiliar with the progress which has of late been made in renal surgery, it may still seem strange that these cases were both operated on before any tumor could be felt in the abdomen. The immediate relief from pain, cystitis, and irritable bladder, in one case amounting to incontinence of urine, is as remarkable as the freedom from pyrexia and general constitutional disturbance after this apparently severe operation. Statistics of nephrectomies clearly show the safety gained by first draining the dilated organ before proceeding to remove it; and he is inclined to think that the ventral or transperitoneal operation will one day be regarded as a scarcely justifiable operation for pyonephrosis.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Fixation of Movable Kidney by Scratching its Capsule Through the Loin.

Dr. J. Greig Smith thus writes in the *Lancet*, July 5, 1884: At present, when the subject of displacements of the kidney is exciting considerable interest, notes of the following case, which was operated upon about a year ago, may be acceptable:

M. W——, aged thirty-nine, a largely-developed, well-nourished married woman, was admitted to the Bristol Royal Infirmary, under Dr. Spencer, in April, 1883, complaining of pain in the bowels, want of appetite, and constant headache. Six years previously she had suffered from a severe attack of inflammation of the lungs, and a month later she was confined of twins. Up to this time she had been strong and well, and her troubles came on subsequently. A year before admission she noticed a tumor in the abdomen on the right side, usually under the ribs, but occasionally low down near the crest of the ilium, or at intermediate points. It was the source of constant worry to her, causing her considerable pain as well as mental anxiety, and she laid on it the blame of all her troubles. There were no other symptoms of importance beyond a yellow discharge from the vagina, which was found to arise from endometritis, and which soon disappeared under the ordinary remedies. Dr. Spencer having effected no improvement by medicinal treatment, and the patient being most anxious to have something done, I was requested to see her. The patient was almost melancholic, with an anxious and worried expression of countenance. The abdomen was lare and pendulous, but thick-walled, and the tumor could not be very definitely made out. It could be moved freely in every direction on the right side of the middle line, and could be made to disappear under the crest of the ilium. It corresponded in shape and consistence to the kidney.

Dr. Spencer's diagnosis was floating kidney with dyspepsia, and he thought that the one caused the other. Personally, though I was bound to admit that all the signs were consistent with floating kidney, yet I thought they just as consistent with solid ovarian tumor with a long pedicle. Two other cases which I had seen, where diagnosis of floating kidney was made, turned out, one on the post-mortem table to be horseshoe kidney, and the other, on my removing it, to be solid ovarian tumor. The facility with which this tumor could be pushed down into the pelvis suggested the possibility that it also might turn out to be ovarian, and I recommended abdominal section, to remove it if not renal, to fix it if renal. This was accordingly done, and the tumor was found to be renal. There was no mesonephron proper, and the kidney was found very freely movable, partly in the midst of, partly with, a sort of flaccid bag of peritoneum and fat. When replaced it could be made to bulge in the loin, where it was readily felt through the skin and muscle. I hoped to be able to stitch it subcutaneously by carrying a long, curved-handled needle through the skin and the surface of the kidney, and tying the catgut suture over the muscles after making a punctiform incision in the skin. But the surface of the kidney tore and afforded no hold to the needle; so with one hand still in the abdominal cavity pushing out the kidney and ascertaining the course of the needle, and the other holding the needle outside, I moved the kidney surface in several directions over the point of the needle, and left it *in situ*. I hoped that the organized inflammatory material so produced would be strong enough to retain the kidney in position.

The case pursued the ordinary course of a successful abdominal section. The antiseptic dressings were removed in a week; the wound was found completely healed, and the stitches were removed. On the fourth day there was a small amount of blood in the urine. All pain from the tumor was gone immediately after the operation, but about six weeks afterwards she suffered from diffuse irregular attacks of abdominal pain, not in any one spot, but generally all over. At this time she had abnormally frequent calls to micturate, and these extended over some weeks. The tumor remained *in situ*, however, and there has been no sign of its reappearance since. I cannot say, however, that the operation has benefited the patient very much. She is nearly as low-spirited as ever, and though there is less abdominal pain than before, there is still a good deal, and the calls to micturate are still abnormally frequent. Possibly the near advent of the menopause may partially explain her symptoms.

Remarks.—I am no advocate of operative procedure in case of either movable or floating kidney, and what was done in this case was rather as a sequel to an exploratory operation than as a deliberate attempt at fixation of the kidney. It would have been easy to stitch the kidney to the abdominal wall; but it is difficult to believe that an unprotected position, close to the surface of the abdomen, and in contact with its constantly-moving walls, can be much better than free movement inside the abdominal cavity. Again, I might have cut down on the kidney in the loin, and stitched its capsule to the tissues in the neighborhood. This would have added to the danger of the operation, and would have rendered only the immediate result more certain, for sutures fixate only as long as they exist. When these are absorbed, the adhesions only remain to connect the united surfaces, and if the artificially inflamed capsule is kept in position while the adhesions consolidate, the effect of sutures might be got. In this case, now that a year has passed, we may assume that the desired result has been attained. In another case I should give a thorough trial to treatment by rest in bed, and carefully applied padding inside an abdominal belt. If this failed, I should perform nephrorraphy by lumbar incision. But a case such as the above teaches us not to be too sanguine as to the immediate good result of fixation, and should warn us to hold our hands for a long time, unless the local symptoms were very urgent indeed.

Dislocation of First Lumbar Vertebræ Successfully Reduced.

Before the Clinical Society of London (meeting March 28, 1884):

Mr. N. Davies-Colley read notes of this case. A shipwright, aged 55, was stooping at his work, when a mass of iron, weighing 7 cwt., fell upon the small of his back. He was at once admitted into Guy's Hospital. He was collapsed, but quite sensible. The spine of the first lumbar was three-quarters of an inch to an inch behind that of the last dorsal vertebra. The adjacent spines were even, and formed a continuous series, those above at a level considerably anterior to those below. There was no motility nor crepitus to be detected upon gentle manipulation. He could move his legs, but the right somewhat less than the left. There was impairment of sensation on the outer side of the right leg, and complete loss upon the dorsum of the right foot. Soon after admission extension was applied under ether. Mr. Davies-Colley kept his hand upon the prominence while three assistants made traction upon the legs. The projection was thus gradually reduced without any jerk; at the same time some crepitus and motility could be felt in the last dorsal spine. A plaster-of Paris jacket, similar to the laminated form recommended by Mr. Furneaux Jordan, was applied in the horizontal position, while traction was still being made upon the man's legs. When he recovered consciousness, he was quite comfortable. A more careful examination, two days later, showed that the right musculo-cutaneous nerve was completely paralyzed, and there was some loss of sensation between the first and second toes, where they are supplied by the anterior tibial nerve. For ten days he was unable to micturate, and some small bed-sores formed over the sacrum, although within two days of the accident he could turn over in bed and lie upon his side. On the thirty-fourth day after the accident, the splint was removed. The line of the spine was then quite even. There was no deformity, and little, if any, tenderness. In less than two months after the accident he was able to walk; but he was still unable to evert his right foot. With the help of faradization, he gradually recovered power and sensation; and when he was last seen, in October, no difference could be detected between the movements of the two legs, and the only abnormality in sensation was a slight numbness in the middle third of the outer side of the right leg.

Mr. Bryant, after remarking on the great interest of the case just related, said that the practice therein recommended was hardly sufficiently recognized. He had seen three cases of supposed fracture of the spine in the practice of his colleagues benefited by extension, and had had two cases under his own care where the treatment had been adopted successfully. One of these was that of a man, aged 74, who was brought to the hospital an hour after a heavy sack had fallen on to the nape of his neck. There was paralysis from the nipple-level downwards, no loss of sensation, slight priapism, and great pain in the right half of his body. There was projection of the third dorsal vertebra, with swelling around, and some separation of the spinous processes; there was also fracture of the sternum. Extension was applied, a sudden jerk was distinctly felt, and was audible to the bystanders; the deformity was completely relieved, and so was the pain, which had been extreme. The next day some movement of the toes and of one foot was possible, but on the following day the anæsthesia had increased, and was complete the day after, and he died from respiratory troubles on the seventh day. The examination confirmed the diagnosis of dislocation of the third dorsal vertebra, which was found to have been completely reduced; there was some extravasation of blood into the spinal cord, but not enough to have produced permanent disorganization, and had the patient been younger he might have made a complete recovery. He wished to advocate very strongly the treatment of such cases by extension.

Mr. Howard Marsh referred to a case of Mr. Willett's at St. Bartholomew's Hospital, wherein there was dislocation of one of the lower dorsal vertebræ; extension had brought about replacement, and after death the dislocation was proved to have been completely reduced; but he could give no details.

Mr. Durham had seen Mr. Colley's case throughout, and congratulated him on the result. He did not now regard these cases as so hopeless as he was taught to consider them in former days. He thought that there was some danger in the use of plaster-of-Paris jackets in these cases, except in the late stages, on account of the risk of producing sores, which would be unrecognized and inaccessible.

Mr. Davies-Colley agreed that the jacket would be objectionable, if with a fracture of a dorsal vertebra there was loss of sensation below the umbilicus.

The Actual Cautery in Diseases of the Joint.

In the *Lancet*, May 10, 1884, we read that on the recent occasion of a patient being brought into the operating theatre of King's College Hospital for the purpose of undergoing treatment by actual cautery for disease of the knee-joint, Mr. Henry Smith made some remarks on the employment of this agent. He stated that, whilst in former times the actual cautery had been employed to a considerable extent by surgeons, it had gradually fallen into disuse, in consequence probably of the seemingly cruel and painful nature of the operation, so graphically described by the late Sir William Fergusson in his "Practical Surgery." Since, however, the introduction of anæsthetics, by means of which this potent remedy could be applied without the horrors formerly accompanying it, the actual cautery had been resorted to without scruple, and the pupils attending his class had had recently several opportunities of witnessing the extraordinary benefits produced by its application. He desired to call attention to two other instances of disease of the knee-joint, occurring in females, where the effect of one application of the actual cautery had been remarkable. In one of these cases the disease had been of long standing, the joint being in a state of chronic inflammation, the chief symptoms being severe pain on any attempt to move it, and some swelling. After the employment of various measures, which were of little use, the actual cautery was freely applied, with almost immediate

relief and ultimate cure. In the other case, that of a woman who had been suffering from chronic inflammation of the femur, which had implicated the knee-joint, and resulted in great enlargement of the bone and anchylosis of the joint, attended with most severe pain and total loss of use of the limb, no treatment seemed to be of any avail until the cautery had been freely used over the end of the femur and knee, and those present had been able to witness the effect of this agent, which resulted in immediate and permanent relief. In another case which had been before their notice, that of a young woman with disease of the hip-joint, the symptoms denoting progressive disintegration of the articulation, the usual treatment was adopted—namely, rest, extension, and local applications—but although the acute symptoms were relieved, intense pain persisted, especially at night. The actual cautery was applied, and the effect was to mitigate the pain within a few hours, and ultimately the course of the disease was arrested. Another striking instance of the good results produced by the cautery had recently been under their notice. It was the case of a poor woman who had suffered for some time from disease of the spinal column in the dorsal region. There was some curvature, very severe pain on pressure over three of the vertebræ, and latterly the woman had lost control over the bladder. After she had been kept at rest for some little time, and the more urgent symptoms had been relieved, he applied the actual cautery freely over the diseased vertebræ, and at the same time administered mercury internally, so as to produce gentle ptyalism. The effects were almost immediate: pain was relieved within a few hours, the bladder symptoms were removed, and in the course of six weeks the woman left the hospital convalescent, having been previously fitted with a Sayre's jacket. In an instance, also, of disease of the ankle-joint in a strumous lad, where the features of the case pointed to mischief in the bone rather than in the synovial membrane or cartilage, he was on the point of amputating the foot, but before doing so, he determined to apply the cautery freely. This was done under ether, and with such good results that the patient left the hospital with a stiff ankle but a serviceable foot.

Mr. Smith said he was anxious to draw their attention to one important point in connection with this means of treatment. It should not be used in instances where acute inflammatory action existed; it would be necessary to abate the acute symptoms before using the cautery. In all the instances alluded to this had been done, and the actual cautery was then applied; in fact, as he had often pointed out to the pupils in the wards, it was in those instances where the chronic inflammation was going on, threatening progressive disintegration of the joint structures, and especially those instances where constant pain was a notable symptom, that the actual cautery was such a powerful help to the surgeon; and he strongly advised its use in such cases before resorting to more severe proceedings.

Gastrostomy.

After reporting a successful case in the *American Practitioner* for May, 1884, Dr. S. W. Gross says:

A personal experience with two cases and a thorough knowledge of the literature of the subject have convinced me that gastrostomy is not only easy of performance, but that it should be resorted to in all cases of carcinoma of the esophagus as soon as dysphagia has set in, for the double object of alleviating suffering and prolonging life. The best incision to reach the organ is that of Bryant, which commences at the outer border of the rectus at the level of the eighth costal cartilage, and is carried for three inches below the borders of the ribs toward the apex of the tenth cartilage, the movable tip of the latter on the ninth cartilage being a capital guide for the termination of the incision. Unless there is imperative need for opening the stomach at once, it will be wise to divide the operation into two stages, so as to insure perfect union of the peritoneal surfaces, and thereby prevent peritonitis from effusion. To effect this object, the stomach should be stitched to the wall of the abdomen by an outer row of pure silk sutures, as recommended by Howse, in addition to the sutures inserted through the viscus and the edges of the wound, care being taken not to penetrate the cavity of the stomach, lest its contents may pass through the punctures and light up peritonitis, as happened to Volkmann. The opening in the stomach, which may be made after the lapse of five or six days, should not be longer than a quarter or the sixth of an inch, and in making it the organ should be steadied by the two threads or wires inserted at the first operation near the center of the exposed portion. For feeding, an elastic tube of sixteen or eighteen millimeters in circumference may be permanently retained in the opening, but it should be renewed at least every four days.

Gastrostomy for carcinoma has been resorted to at least one hundred and fifty-eight times. Forty-two of the subjects perished as the direct or indirect result of the operation; twenty-one from peritonitis, eleven from pneumonia, bronchitis, and pleurisy, five from shock, four from phlegmonous gastritis, and one from renal convulsions. The mortality may therefore be placed at 26.58 per cent., which is not large when the exhausted condition of many of the patients at the time of its performance is taken into consideration. Two additional cases succumbed, one from hemorrhage from the growth, and the second from suffocation due to perforation of the trachea, while sixty-five died of exhaustion, starvation, or extension of the disease, at periods varying from nine hours to one month; in fourteen the second step of the operation was not completed. Of the entire number, 109 died in one month; four were living, but how long can not be determined, and forty-five survived longer than one month, the average duration of life after the stomach was opened having been thirty-three days.

Of the forty-five survivors, twenty-seven expired subsequently: two in five weeks, two in seven weeks, eight in two months, two in two months and a half, three in three months, two in four months, two in five months, one in six months, one in seven months, one in seven months and a half, two in eight months, and one in ten months. Of the remaining eighteen, three were living at the end of one month, two at forty days, one at seven weeks, three at two months, two at three

months and a half, two at four months, one at five months, one at six months, one at seven months, one at twelve months and nine days, and one at thirteen months. The last two cases were under the charge of Mr. Walter Whitehead, of Manchester, England, who was kind enough to write me that the first could not live much longer, while the second was still enjoying excellent health.

The Treatment of Sea-Sickness.

Dr. T. T. Reynolds thus writes in the *Lancet*, June 28, 1884:

With regard to the symptoms of sea-sickness, I only need mention those which bear on its etiology and treatment. The first is excessive glandular action, the salivary glands being those soonest affected. Efferent empulses from the secretion centre in the medulla, descend by the chorda tympani, and excite this salivary secretion. Now, we know that atropine paralyzes the secretion centre in the medulla, and if given early in sea-sickness we find it cures the affection. A drop-dose of liquor atropiæ sulphatis, B. P., in a teaspoonful of water, should be given every hour till the physiological effect of the drug is produced. The sedative action of atropine on the medulla renders altered sensory impressions inoperative in producing sea-sickness. It should be given early in the affection, as when the more advanced or secondary stage is reached, its effect is not so marked, though still beneficial. In some cases sugar is found in the urine, due probably to the irritation of the diabetic centre in the medulla. Four minim-doses of Fowler's solution thrice daily is the best treatment in such cases. When called in after the affection has lasted two or three days, the medical man generally finds the patient greatly depressed, with a furred tongue, bowels obstinately constipated, pulse quick and weak. The best treatment of this stage is to have the bowels well moved by enemata. The atropine should be given as above, and the patient's strength supported by drachm-doses of a mixture composed of equal parts of brandy and iced water. The dryness of the throat caused by the atropine will be best relieved by small quantities of ice or iced lemonade. Valentine's meat juice or cold beef-tea, "a little and often," will sufficiently nourish the patient till more solid food is relished. Bromides, like atropine, have a sedative action on the brain, but, to prevent sea-sickness, must be given in sufficient quantities to produce bromization. Now, as bromism is a very serious condition, and one liable to affect a patient's reason and general health most injuriously, the bromides should be used with great caution, and only when prescribed and their action watched by a medical man. A late New York physician published a book on sea-sickness for the general public in 1881, in which he recommends travelers to "purchase a pound" of the bromides of potassium or sodium, and to take as much as ninety grains a day before coming on board, and to keep up a bromized condition during the voyage. This is dangerous advice, and the public should be warned against adopting it. I have seen lamentable results follow such abuse of the bromides. One case was that of a clergyman, who had taken ninety grains daily two days before coming on board and two days afterwards. I was called to see him during the night of the fourth day. He was insane, unable to remember, subject to illusions, and incoherent in his talk. This condition lasted seven days. Two business men of New York also came under my care, suffering in a similar manner. Both were married men, and the bromization rendered them impotent for some months, and also incapacitated them for business. In such cases of bromide poisioning, I find nourishing food, with small quantities of brandy and sal volatile, at regular intervals, the best treatment. Chloral hydrate is a useful drug in some cases of sea-sickness; its curative action seems to depend on its rendering the brain anæmic, as we find that the vaso-motor centre in the medulla is affected in the same way after loss of blood and under chloral.

Injections of Glycerine and Carbolic Acid for the Preservation of Bodies for Dissection.

Dr. O. T. Freer thus writes in the *Chicago Med. Jour.*, July, 1884:

During a course of dissection in the anatomical department of the University of Munich, I observed that the material showed a remarkable resistance to decay, being still fresh at a period when the average subject of Chicago's dissecting-rooms is too much decomposed for use. The parts which I was dissecting were in almost as perfect a condition after exposure to the air of a warm room for from two to four weeks, as when they were first given me; and those portions from which the skin had not been removed, remained entirely unchanged.

On inquiry, I learned from Professor Rudinger, Munich's anatomist, a man who has written numerous valuable works and done much for science by his original researches, that he preserved his subjects by injecting into the femoral artery a mixture of glycerine, carbolic acid, and alcohol, a method invented by himself and used here since 1872.

Since its introduction he had seen no bad effects from dissection wounds here.

He said that, according to the amount of injection material used, subjects would keep from two to six months in a summer temperature, the only necessity being moisture to prevent mummification.

The solutions used by Prof. Rudinger are:

(*a*) For preserving bodies for long periods, three to six months: Glycerine, 40 parts; carbolic acid, crystalized, 11; alcohol, 8.

(*b*) For preserving bodies from two to three months: Glycerine, 80 parts; carbolic acid, 17; alcohol, 13.

The amount injected varies according to the length of time it is desired to preserve the subject, from two to four litres being ordinarily used; but an average body will readily contain six or more.

The advantages of this method are, that the tissues preserve their natural appearance and pliancy from the commencement of an ordinary dissection to the end. Students, therefore, need not hurry their dissection, even in warm weather, as decomposition is so slow that the parts dissected last are in as perfect a state as those seen first. The solutions mentioned above do not whiten the tissues, which retain their natural appearance to the end.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

ANTIPYRIN.

Knorr, in Erlangen, has manufactured from chinolin a new alkaloid, called, on account of its antipyretic effect, antipyrin. Dr. Paul Guttmann, in Berlin, has recently investigated its effect, and published the results of his observations in the *Berl. Kl. Woch.*, 20, 1884.

He made use of the drug fifty-seven times, in twenty-seven patients laboring under a high temperature. The cases experimented upon were as follows: 6 fibrous pneumonia, 6 typhoid fever, 2 scarlatina, 2 febris recurrens, 2 erysipelas faciei, one each of variola, morbilli, pleuritic exudation, erysipelas cruris, and abscess of the arm, and 4 of pulmonary phthisis with continually high fever. The temperature was usually taken in the rectum, in a few cases in the axilla, and generally every hour during the day, and every two hours during the night.

The results teach that antipyrin, in the dose of 64 to 96 grains, has a certain and high antifebrile effect, at least lasting five hours, and often much longer. It is best to administer the remedy in two or three doses, each of 32 grains, given every hour in watery solution, to which some corrigens for the taste has been added, or in powder form in wafers.

The temperature sinks continually and gradually, already one hour after the first dosis, at least by half a degree, and then goes on falling, until two hours after the third dosis, five hours after first, the decline has usually reached its height, and mounts up to 30. Sometimes the effect continues for eighteen hours. When later the temperature ascends again, it also does so slowly and gradually. The same effect can be achieved by one single dosis of 64 grains, and also by five consecutive (every hour) doses of 16 grains each.

Together with the temperature, the frequency of the pulse declines. In cases where the decline in temperature is great, active perspiration is apt to occur. Disagreeable effects were not observed; only in one case vomiting ensued. Generally the remedy was well borne, even in cases where quinine caused emesis.

Antipyrin has, therefore, a great advantage

compared to kairin. The latter produces its temperature-decline by a rigor; its effect is sudden, and lasts but a short time, when temperature again rapidly ascends. Antipyrin has a similar effect to quinine, but as it is much cheaper, and is generally better borne by the stomach than quinine, its general adoption as an antipyretic, in preference to quinine, can be recommended.

THE VIVISECTION QUESTION.

The discussion on vivisection has become one of the popular literary topics of the day. It offers a good theme for affecting sentiment. *Lippincott's Magazine* had a leading article on it in its last number—*against it*, very pointedly.

In the London *Illustrated News* on the other hand, George Augustus Sala says something in defence of it in his happy style. His words are:

"I was, in early childhood, that which I once heard my mother's maid, in conversation with a friend, describe me as being 'a miserable little hobject;' and the doctors were continually doing things to me. I am, in many respects, a miserable object now, and require to be periodically patched up by the faculty. And I will say naught against vivisection, because I never yet met with a cruel doctor, and because I firmly believe medical men to be among the most humane, the most generous, the most unselfish of mankind; and I indignantly denounce the imputation that there are any members of a noble, a high-minded and a beneficent profession who, actuated by no more exalted motives than their 'greed after the hidden things of the life of the flesh,' confessedly and without compunction torture dumb animals. The medical man practices vivisection (with the smallest possible infliction of pain on the animal vivisected) not because he is selfishly greedy after 'the hidden things of the life of the flesh,' but because he wants to find out what is the matter with you, verbose sir, or sentimental madam; because he is striving his utmost to devise means for saving you from misery and anguish; for mitigating the agony of the ills that rack the joints or fire the veins, or that 'in the deeper vitals rage.' He is no worshiper of knowledge as of an idol. He tries during his whole laborious life to learn more and more, in order that he may console and relieve and preserve suffering humanity."

That there is truth as well as good writing in this extract, all must admit.

One of the latest conquests of vivisection is that it has demonstrated that diseased lungs, or portions of them, can be removed from living animals and human beings. At Naples, out of sixty-three animals operated upon in this manner, thirty-six recovered.

CAFFEIN IN DISEASES OF THE HEART.

Gubler, 1877, first reported that there are certain cases of heart disease, associated with dropsy, where caffein has a far more powerful effect than digitalis. Many reports have since confirmed this statement. Dr. X. Francotte has recently once more investigated the action of caffein (*Deutsch. Med. Cent. Zeit.*, June 7, 1884). He shows by the records of six cases, that when digitalis has no longer any effect, caffein may still save life. Its main action consists in a greatly increased diuresis. The dose has to be gradually increased. Its effect on healthy persons seems to be *nihil*, for sixteen grains per diem have been taken without their causing the least effect.

Dr. Kobert, who also has experimented with the drug, comes to the conclusion that caffein, while exerting no influence in normal conditions, acts as a strong diuretic in some cases of heart disease with failing circulation. He further says, that caffein cannot be compared with digitalis, as it never shows any accumulative effect, does not act at all on healthy persons, and greatly stimulates the function of the cases only when the effect of digitalis has ceased.

Notes and Comments.

The Action of Digitaline.

From the *Lancet*, July 5, 1884, we learn that M. Kauffmann, of Lyons, working in M. Chaveau's laboratory, has studied experimentally the physiological action of digitaline (amorphous), and embodied his results in an interesting paper contributed to the *Revue de Médecine* of May 10. His experiments are all the more valuable in that they were made upon the higher animals (dog, ass, and horse). He finds that locally digitaline acts as a powerful irritant, which renders it unsuitable for administration by the skin, whether intact or denuded of epidermis, the inflammation excited by

the substance preventing absorption. It has similar irritant action on mucous membranes, and the stomach can only tolerate minute quantities. For the same reason, only very dilute solutions (1 in 500 or 1 in 1,000) are available for subcutaneous injection. He found that absorption took place most readily by the respiratory mucous membrane, next by the gastro-intestinal, next by connective tissue, and least by muscle—the febrile reaction ensuing on injections into the last two named tissues masking the specific effects of the drug. The results of all his experiments as to the general action of digitaline are partly at variance with accepted teaching, particularly as to its effect on the renal secretion; for he finds that in healthy animals digitaline, whether given in large or small doses, does not produce diuresis. Administered hypodermically or in the form of powder in the stomach, it causes a diminution in the quantity of urine excreted, and an increase in the amount of urea. Given by the stomach in the liquid form and in small doses, it diminishes both the quantity of urine and of urea. It only produces diuresis in dropsies due to disorders of the circulation. Of its physiological action on the circulatory organs he declares that in small doses digitaline slows the pulse, but in larger doses accelerates it; and he attributes the former effect to stimulation of the medullary and intra-cardiac centres of the moderating system, the latter—*i. e.*, acceleration—in central and peripheral paralysis of the system. The intra-cardiac pressure, both diastolic and systolic, is increased, and also the energy of the cardiac contraction. The action of the heart is more regular when accelerated than when slowed by digitaline, whilst the pulse is stronger with small doses of the drug than with large. Small doses slightly raise arterial tension by central and peripheral stimulation of the vaso-motor nerves; stronger doses at first increase, then diminsh the tension. The rate of arterial blood-flow is diminished, and the rectal temperature is lowered.

Iodide of Potassium in Pneumonia.

From the *Lancet*, July 5, 1884, we learn that Dr. Luigi Gualdi, of Rome, gives the iodide in forty-centigramme doses every two hours, at the same time applying the ice-bag over the seat of pulmonary inflammation. In thirty-nine cases in which he practiced this treatment, he had excellent results. In all, without distinction, he observed that the sputum, from being viscid and tenacious, became, before the second day, fluid, resembling bloody serum; that with the cessation of the fever the exhaustion also ceased, although the physical state of the lung was not improved—nay, in some cases aggravated; and, finally, that in all the convalescents the appetite was so sharpened that the ordinary diet had to be considerably increased. The mortality was six per cent., while of the two who died one could not be included in the calculation, because, being affected with pneumonia of the apex with furious delirium, he took only two grammes of the iodide of potassium. It is worth remarking, continues Dr. Gualdi, that the fever and the exhaustion ceased, although the physical condition of the lung remained unchanged, thereby confirming Schwartz's position, that the fever is independent of local alterations; also Jürgensen's contention that the cause of the exhaustion resides not in the change in the lung, but in the fever, seems to be similarly confirmed. Dr. Gualdi concludes that from his experience the treatment by the iodide succeeds better with the youth of either sex than with adults; that the iodide should be exhibited at the beginning of the disease, to insure an immediate and perfect result; that the iodide is efficacious over the fever and the exhaustion, but not over the localization, which latter indeed may even be extended under the treatment; that the iodide and potassium combined separate in the organism, so that each has its special virtue; and, finally, that the action of the ice is secondary, inasmuch as it operates on the effects, and not on the cause of the disease. It is useful in the congestive stage; hurtful when the contents of the air-cells are already solidified and the lung indurated.

Unusual Weight of Fœtus at Full Term.

Dr. Edward Gordon reports this case in the *British Medical Journal*, April 5, 1884:

On March 16, a lady, aged thirty-five, primipara, tall, healthy, and well built, gave birth to a well-formed female child, weighing eighteen pounds and measuring twenty-six inches in length. Delivery was effected by forceps, and presented no unusual difficulty till after the head was born, when the shoulders wedged between the coccyx and the pubic arch; by bringing out each arm they were released. The pelvis now lodged in the same place as the shoulders, and was only liberated after a severe struggle, by compressing the iliac bones of the fœtus. The passage, even of the thorax and abdomen, was effected only by great effort. There was just a twitching of the nose and lips of the child after

birth. The placenta was expelled in ten minutes afterwards. A binder was applied and one drachm of ergot administered. The pulse was 80. The patient seemed exhausted, but fully conscious. Artificial respiration, warm bath, brandy, etc., failed to resuscitate the child, although persevered in for half an hour. Unfortunately, the patient, on asking if the child were dead, was answered in the affirmative by an attendant, and at once threw up her hand, exclaiming, "Then I shall die too." She died two hours and a half after the extraction of the fœtus. The immediate cause of death seemed to be syncope from shock, by the news of the death of the child after such a severe and laborious extraction.

Perhaps the extraordinary size of the child may be, in some measure, accounted for by the inordinate appetite of the mother. She herself informed me, during the labor, that she had often eaten a pound of raw meat at a time, took little or no exercise during the last six weeks, often lying in bed till eleven o'clock, and again lying down at three in the afternoon till six. I am informed by a relative that, on one occasion, she ate three pounds of pork at one meal during the latter part of her pregnancy. The lady had made a note of the date since the last menses were seen, which made the fœtus exactly nine months on March 16.

The Treatment of Cholera Infantum.

Dr. James Craig, of Jersey City, publishes a paper on this subject in the *Archives of Pediatrics* for March 15, 1884, in which he says that the treatment of cholera infantum varies very much, and depends upon the physician's ideas and experience. The indications are to prevent nausea and vomiting, support the strength, and check the diarrhœa. If nursing, no change in diet is made, but care should be taken not to nurse the child too often or too much at a time. If bottle-fed, the milk is stopped, and stale bread, soaked in hot water, with a little sugar and brandy added, or Robinson's prepared barley, or arrowroot, made with water, given in small quantities, answer a good purpose. Milk is also prohibited where the child is weaned, but is gradually resumed as it improves. Where the child is weak, one teaspoonful of brandy to six or seven of water, a teaspoonful of which is occasionally given. Where a more powerful stimulant is required, carbonate of ammonia, in one or two grain doses, mixed in syrup of adacia, is used according to the age of the child.

For the gastric and intestinal derangement, his favorite prescription is:

℞. Liq. acidi carbolici, 5 per cent., ℥j.
Bismuthi subcarb.,
Pepsini sacch., āā ℥j.
Aq. cinnamomi, ℥iij.
Syr. aurantii cort., ℥ij.

M. Sig.—A teaspoonful every two or three hours until relieved.

He also applies a spice plaster over the abdomen composed of the following:

Powdered cinnomon, cloves, nutmeg, ginger, allspice, of each, ℥ij.; honey and glycerine, of each, ℥vj.; white of one egg.

M. And spread on cheese cloth or fine mosquito netting. It may remain on over the region of the stomach and bowels for hours or days without blistering—it merely reddens the skin, and is an excellent counter irritant. A bandage should be applied over it to keep it in place.

Change of air frequently brings about convalescence in a very short time. When that cannot be had, the next best thing is to take the child out daily for an hour or two at a time, early in the morning and late in the afternoon. While in the house the child should be kept in a well-ventilated room, free from draughts.

Cystic Tumor of the Thyroid Body.

The following case (which Dr. J. Sidney Hunt reports in a foreign exchange) may, perhaps, be of interest:

At six o'clock on the evening of June 9, he was asked to see a woman who "was taken with a rising in the throat," and was thought to be choking. He found the patient (a woman about forty-six years of age) in an agony of dyspnœa—loud stridulous inspiration, and lividity of face, etc. She had a lump about the size of an orange in the situation of the thyroid isthmus. This lump was stated by a neighbor to have increased in the course of a few minutes from the size of a walnut. There was, however, nothing peculiar in the appearance of the tumor, which looked like a *goître*, and he concluded that the appearance of sudden enlargement was due to the general engorgement of the neck. The *goître*, in fact, appeared to be an accidental complication of a case of laryngeal obstruction or spasm. In a few minutes, chloroform and nitrite of amyl were obtained. The patient was by that time senseless, livid, and making a few last desperate efforts at respiration. Both the nitrite of amyl and the chloroform were tried, with artificial respiration, but without the least effect. The most vigorous efforts

at artificial respiration failed to draw air into the chest. The lump of unknown nature, in front of all the available part of the larynx and trachea, prevented him from making any attempt to open the windpipe. The time from the first symptom of dyspnœa to the moment of death was about ten minutes.

When, at the post-mortem examination, the lump in question was removed, it turned out to be the isthmus of the thyroid gland, hollowed out into a ragged and irregular cavity containing recent blood-clot. The sides of the cavity were covered with old and partly-organized clot. The trachea was flattened from before backwards, from pressure of the tumor upon it. The cause of death was evidently the effusion of blood into the cystic tumor (thyroid cyst?), either directly by pressure on the trachea, or indirectly by pressure on the recurrent laryngeal nerves, causing spasm of the glottis. The larynx was healthy. The trachea was, as before mentioned, flattened from before backwards, especially the second, third, and fourth rings, which corresponded to the greatest size of the tumor.

Arsenic in Gastric Ulcer.

Of course, we all know that regulation of the diet is of paramount importance in the treatment of gastric ulcer. But, making due allowance for the great improvement which always follows the regulation of the diet, Dr. John Strahan (*Brit. Med. Jour.*, June 21, 1884,) thinks the treatment by small doses of arsenic gives results to be obtained by no other mode of treatment. More than, at the outside, two drops should never be given, as the irritating action would then commence to the injury of the patient. By an action on the end organs of the gastric nerves, small doses relieve the pain wonderfully, and improve the general tone of the gastric mucons membrane, curing the gastric catarrh which exists at least in the immediate neighborhood of the ulcer, and thus relieving the patient of the vomiting of mucus, which is sometimes an important feature of the case. We also know that a weak solution of arsenic will, out of the body, heal unhealthy ulceration, *e. g.*, cynchia, or even when given internally, so that it is not strange that it should act locally as a cicatrizing agent on a gastric ulcer. Nitrate of silver, the next best remedy, recommended by such men as H. C. Wood, Da Costa, and Wilson Fox, is not nearly so efficacious, either in relieving the pain or in promoting cicatrization. Indeed, in all gastric and intestinal affections in which nitrate of silver is so much recommended and is so successful, he believes that the small dose of arsenic is far more valuable, and it is certainly far more convenient. Bismuth is highly recommended by Brinton and many high authorities, but it has been recently said that it very often owes its powers as a sedative to the stomach, to a trace of arsenic which it contains.

Spina Bifida Cured by Elastic Ligature.

The *Lancet*, May 17, 1884, tells us that Dr. Antonino Turretta has republished, from the *Giornale di Clinica e Terapia*, of Messina, a case of spina bifida successfully treated by the elastic ligature. His aid was requested for a female child two months old, apparently in good health. She had a tumor as large as a small apple in the middle line, opposite the two last cervical vertebræ. It existed at birth, and had since slowly increased. It was supported by a pedicle which measured an inch and a half in circumference. The covering skin was very thin, and of bluish-red color. The tumor was soft, flaccid, and fluctuating; under strong pressure it diminished somewhat in size; the child cried, and slight convulsive movements were excited in the limbs. No other deformity was present, neither was there paralysis of any organ. An exploratory puncture at the base of the tumor with a trocar gave exit to a thin transparent liquid of alkaline reaction. The tumor shrank, and the aperture was closed with iodoform collodion. Distension and fluctuation were again perceptible in twelve hours. The tumor having been half emptied by another puncture, its pedicle was constricted with a couple of turns of elastic ligature. At the moment of constriction the child cried, the face became livid, and some clonic movements were excited; but in a few hours the patient took the breast and rested. The next day vomiting was persistent, there was a tendency to coma, and twitching of the upper limbs. The condition on the third day was unchanged, and a small dose of calomel was given each day. All these symptoms had subsided on the sixth day, and the ligature with the tumor separated on the twelfth day, leaving a granulating surface, which gradually contracted. The cicatrix was complete and the child cured on the twenty-seventh day.

Phosphorus in Tubercular Disease.

In the *Brit. Med. Jour.*, June 21, 1884, Dr. John C. Thorowgood tells us that he has employed phosphorus as well as the hypophosphites of potash and soda, and under the influence of these prep-

arations he has seen pleuritic thickenings melt away. Old-standing consolidations of lung, that had existed for one, two, or three months, he has seen at once begin to move and disperse as soon as the hypophosphite of potash was given; and cases that have appeared to himself and others very like acute tubercle in the lungs have sometimes recovered on the hypophosphite treatment.

He commenced, about twenty years ago, with phosphorated oil as a medicine; but, owing to its nauseous taste, he took before long to the use of the hypophosphite salts, which contain phosphorus in a very low state of oxidation; and certainly, in those lung diseases which are of inflammatory exudative origin, and apt to run into phthisis, he knows of no remedy to compare with the hypophosphites. Before the discovery of the tubercle-bacillus, he had come to the conviction, from observation, that there were cases of lung disease where something seemed most decidedly to stop the way towards recovery by means of drugs given by the stomach. If inflammation be the sole agent that destroys the lung in phthisis, he should regard very few cases as incurable. It is the bacillus that seems to set the phosphorus treatment at defiance; and he notices at Victoria Park Hospital, that, just when he finds the hypophosphites most helpless, then it is that his clinical assistant finds "lots of bacilli."

A few weeks ago, he turned out as cured a case of unmistakable disease in the upper third of one lung, and in that case no bacilli were found.

The Treatment of Ostitis.

In the *Brit. Med. Jour.*, July 5, 1884, Mr. C. Macnamara thus tersely puts the question of treatment of ostitis: "We must bear in mind the fact that, supposing the exciting cause of tubercle be a bacillus, it is certain that an hereditary predisposition, and other recognized circumstances, prepare the soil in which any such influence can take root and grow. Pure air, sunlight, and plenty of wholesome food, are essential to the building up, or fortifying tissues against the action of any causes which provoke the growth of tubercles. If tubercles have formed in a bone, means tending to invigorate the patient's health must be enforced, and at the same time the diseased tissue should be protected from concussion or injury. Rest to the diseased bone is useful, and it should be employed so as to relieve pain caused by the pressure of the extremities of tender parts against one another. But, in my opinion, it is a mistake to suppose that rest, or confinement to a couch or bed for weeks and months, particularly in young children, is a judicious method of treating cases of this kind, especially in the early stages of the disease. I am convinced that the actual cautery, applied judiciously near the seat of the disease, and repeated if necessary, is of great service in many of these cases. In more advanced instances, good hygienic conditions, great patience on the part of the patient, his friends, and the medical attendant, and the removal of diseased bone, together with free drainage, will bring about results more favorable than could otherwise be attained. Subperiosteal excision of the diseased extremities of the bones is sometimes attended with most favorable results."

Ovariotomy in Infancy.

From the *Brit. Med. Jour.*, April 12, 1884, we learn that Dr. Roemer, Assistant-Surgeon to the Augusta Hospital, Berlin, has recently published in the *Deutsche Medicinische Wochenschrift*, a case of ovariotomy performed by him on a child aged one year and eight months. At the birth of the child, the midwife observed that its abdomen was much distended. There was little difficulty in diagnosis, and the pelvis was readily explored through the rectum. The tumor was removed last August, under corrosive sublimate spray; it was "of the size of a child's head," and there was slight adhesion of the omentum. The pedicle was long and thin, and was secured by a double catgut ligature. The right ovary was the seat of disease, the left was perfectly healthy. The tumor was dermoid, containing hair, bone, and cartilage. After the operation, the child was tied gently but effectually on to its cot, and opiates were given when required. It was fed on cold milk and wine. The highest temperature was 101.6°; this point was reached on the evening of the second day. On the fifth, the child's bowels were freely opened by five minims of castor-oil administered twice; on the twelfth, the abdominal sutures were removed. The child recovered perfectly. Dr. Roemer gives the following statistics of ovariotomy performed on children: One of the youngest cases next to his own was under the care of Dr. Neville, of Dublin; the patient was two years and eleven months old, but only survived the operation for two hours. Busch operated on an infant aged two; Alcott on a child aged three; both cases died. Schwartz operated successfully on a child aged four; Barker on two, and Knowsley Thornton on one, aged seven; and Spencer Wells, Cupples, and Chenoweth, each on one child eight years of age.

Exercise for Girls.

The *Brit. Med. Jour.*, March 22, 1884, says:

Several daily papers have recently discussed a letter from Mr. H. P. Dunn, published in the *Standard*, on the use and abuse of gymnastics for young women. The letter, as might be expected, turns attention to the evils of excessive gymnastic training. As violent exercise produces bad results on weak youths, and as girls are, on the average, weaker than young men, it is natural to suppose that injuries to health after gymnastic training may be commoner amongst females than amongst males; and experience shows this to be the case. No doubt the best kind of physical training in youth is voluntary exercise, either in playing at the outdoor sports popular with English boys, or in rambles over fields and hedges. For certain social reasons, not entirely unconnected with physical matters, neither such sports, nor such congenial walking exercise, can be carried out in girls' as thoroughly as in boys' schools, and methodical gymnastics stand to cricket in the same relation as a walk with other fellow-pupils in line and in class does to a pleasant saunter with one or two school-fellows along a country lane. The aim of the authorities at a girls' school should be to allow as much congenial exercise as possible to every pupil, and to encourage physical activity as strongly as cleanliness and deportment; gymnastics are quite secondary to such conditions. Mr. Dunn is right in recommending frequent drilling; but in preferring dumb-bell practice to bar and ladder gymnastics, it must be remembered that severe palpitations are not unfrequently set up by the use of dumb-bells, even when that form of exercise is not disagreeable, and when the subject is apparently free from visceral disease.

The Compatibility of Sulphate of Quinine and Iodide of Potassium.

It having been suggested that when these drugs are prescribed together, or one a short time after the other, owing to their incompatibility, that they will produce anorexia, nausea, even vomiting, or colic. William Martindale writes to the *Brit. Med. Jour.*, July 5, 1884, that such a mixture, with the addition of compound powder of tragacanth, is a favorite with a physician in large practice, yet he never heard any complaint about its effect. Chemically, their incompatibility will depend upon whether the normal sulphate of quinine is dissolved by diluted sulphuric acid added to the mixture or not. No decomposition will occur if the two neutral salts be mixed with water in a fairly diluted condition; in an ordinary dose, some quinine will remain undissolved, as sulphate of quinine. But if diluted sulphuric acid be used to dissolve the sulphate of quinine, the mixture is at first clear; but, on standing, it deposits a reddish-brown powder. Theoretically, this is due to the sulphuric acid reacting on the iodide of potassium, setting free hydriodic acid, which is colorless, but readily decomposes, liberating iodine; and this element, under certain conditions, has a great affinity for sulphate of quinine, forming sulphate of iodo-quinine. The reddish-brown powder which he has mentioned as depositing in the above mixture is not pure sulphate of iodo-quinine. It has been analyzed by Righini (Watt's Dictionary, vol. v, p. 20), and shown to be a mixture of hydriodate of quinine and iodo-quinine.

The Essentials for the Safe Administration of Ether.

Dr. David W. Cheever concludes an article on the administration of ether in the *Boston Med. and Surg. Jour.*, May 29, 1884, by giving the following essentials for its safe use:

An empty stomach.

A loose neck.

A free abdomen; no corsets or skirt bands.

Removal of artificial teeth.

An easy, semi-recumbent position.

A sponge wrapped in towels for the ether.

A gag, and forceps for the tongue.

When stertor occurs, the patient should be tipped forward, the cheek opened with two fingers, the tongue drawn out, the fauces swabbed. To *insure* safety, the surgeon should hear every respiration of the patient.

Anæsthesia from sulphuric ether is of two forms:

1. Primary anæsthesia, which is a moment of confusion coming on after a very few inspirations. At this moment a felon can be opened without pain, and the patient wake at once.

2. Comatose anæsthesia, for prolonged operations. Ether *may* be given almost indefinitely. To relieve the hopeless agony of tetanus, I have had it administered for twenty-four hours.

If you would avoid asphyxia, nausea, and headache, and be *safe*, use only the best and the purest anhydrous sulphuric ether.

Surgical Treatment of Acute Circumscribed Pulmonary Gangrene.

Dr. Christian Fenger, of Chicago, presented a paper on this subject to the late meeting of the

Illinois State Medical Society, from which we extract the following recommendations:

1. The incision ought to be made parallel to the ribs.

2. The ribs must be exsected to a degree sufficient to secure access to the part.

3. In conformity with the suggestion of Albert and Mosler, the needle of a hypodermic syringe should be used as a guide into the cavity, or diseased lung tissue, and the small platinum pole of Paquelin's thermo-cautery should be employed to effect the opening.

4. The cavity must be washed out if practicable. Due care must be exercised to prevent drowning, if the cavity connects with a bronchus. Irrigation of the cavity was productive of no untoward effect in Buhl's case, but was the cause of troublesome cough in Fénger's patient, and Mosler ascribes one death to poisoning from thymol irrigation.

Dr. Fenger is of the opinion that there is no immediate danger of death from the operation, and that it is indicated in cases of acute circumscribed pulmonary gangrene.

Tobacco Amblyopia.

That the excessive use of tobacco has an injurious influence on sight has been amply demonstrated. Dr. Charles Shears contributes a very able article on the subject to the *Brit. Med. Jour.*, June 21, 1884, in which he formulates the following conclusions:

a. Atrophy of the optic nerves is very rarely met with as the result of excessive smoking.

b. Tobacco is the essential agent in producing the failure of sight.

c. Great moderation in smoking, and especially the employment of mild forms of tobacco, is all that is necessary to insure recovery.

In the great majority of cases, no diminutiton in the peripheral field of vision was found. In twelve only were careful observations made with regard to a central defect in the visual field; and, of these twelve, six cases were found having well-marked "central scotomata."

Hydrobromate of Conia in Epilepsy.

We will all at least agree with Dr. R. Norris Wolfenden, when he tells us in the *Practitioner*, (June, 1884), that his experience with bromide of potassium in epilepsy has not been satisfactory, to say nothing of the disagreeable skin eruption which it frequently induces. But we cannot accept positively, until it has had further trial, his recommendation in favor of hydrobromate of conia. While he does not praise it very highly, yet it would seem from the tenor of his article that he has found it more useful than any other drug now in use. The dose is half a grain thrice daily, gradually increased. It would seem to us that those who regard epilepsy as almost always a traumatic disease, so to speak, that is to say, a disease with a palpable cause (palpable when carefully sought for), will have the most success in its treatment. So says Dr. Pepper, and he knows whereof he speaks.

Pasteur on Hydrophobia.

From the *London Med. Record*, April 15, 1884, we learn that the results of M. Pasteur's experiments were presented to the Académie de Médecine, Paris, on February 26. They show that the virus has been found in the saliva, brain, spinal cord, peripheral nerves, and sometimes in the cerebro-spinal fluid. The medulla oblongata of a rabid animal contains an enormous number of very fine granules, which are supposed to be the virus, but which have not been satisfactorily isolated. When the virus is injected into the subcutaneous cellular tissue or into the veins of a healthy animal, the paralytic form of the disease is produced, while the furious form appears after inoculation of the virus upon the surface of the brain. M. Pasteur thinks that the virus may be attenuated by passing through different species of animals, and that immunity may perhaps be conferred on dogs, though on this point the experiments are not conclusive.

Mercury in Pleurisy.

Dr. J. A. McDougall, of Edinburgh (*Practitioner*, June, 1884), believes that mercury will cut short the morbid action in pleurisy. In the case of a feeble and exhausted woman, he gave blue pill gr. ij., with squills and digitalis āā gr. j., night and morning, with the happiest results; and he concludes that if in a case such as this, the subject of which was a broken and feeble woman, in whom acute disease had already induced very pronounced asthenia, one can use with success a drug the debilitating effects of which form in the opinion of many the gravest objection to its employment, the field of its usefulness becomes, in his opinion, a great and wide one. So truly is he convinced of its value, that for many years he has treated no case of pleurisy without its aid.

Elenine for Coughs.

The *Med. Record*, May 31, 1884, tells us that Dr. Valenzuola has recently met with considerable success in the treatment of troublesome coughs

by elenine given in pill-form or in tincture (*El Siglo Medico*). He employed it in bronchitis and phthisis, in doses of one-eighth grain in pill ten times a day, or five drops of the tincture three times a day. In every case he states that the cough was moderated, the expectoration was lessened in quantity and became mucous, and the thoracic pains were greatly mitigated. The drug also increases the appetite and improves digestion. It is possessed of no narcotic properties. Elenine is not a new remedy, for it was known, though but little esteemed, by our fathers. Further trials with this drug will have to be made before the indications for its use shall be sufficiently clear and definite to establish its claims as a reliable remedy for coughs.

Reindeer Tendons in Surgical Practice.

In the *Russkaia Maditzina*, No. 5, 1884, p. 118, Dr. Putiloff, of Omsk, Siberia, recommends threads made of reindeer tendons (used by Ostiaks for sewing their boots, coats, etc.), as a substitute for catgut in surgical practice. The author tried this material (after treatment by ether, to remove fatty acids, and by a five per cent. solution of phenol in absolute alcohol) in a case of epithelioma of the lower lip. The sutures underwent complete absorption by the end of three days. As the author states, the strength of these tendon-threads is very considerable. The price of the article is extremely low.

Laparotomy for Volvulus.

The *Gazzetta degli Ospitali* of June 11 reports that Dr. Medini performed laparotomy in the Ospitale Maggiore of Bologna on the 19th of April last, for twisting of the intestine. The operation was quite successful, and the patient (a male, aged sixty-three), may be considered cured. Notwithstanding the manipulation required to disentangle the intestinal coils, and to separate the adhesions between them, the case progressed without serious symptoms.

Abnormality of the Diaphragm.

At a recent meeting of the New York Pathological Society, Dr. Ferguson presented the body of a colored infant from the Morgue, showing absence of the diaphragm on the left side. The stomach, the left lobe of the liver, the greater part of the small intestine, and the cæcum, were all in the left pleural cavity. The left lung was not developed beyond the size of a hickory-nut, and was emphysematous. The right lung was well developed.

Correspondence.

Multiple Calculi in a Man Aged Sixty-four.

Eds. Med. and Surg. Reporter :—

———, aged 64, presented himself at the "City Hospital," of this city, for treatment for "gravel." He dated the commencement of his urinary troubles back twelve years, and claimed a steady increase of suffering to date of application, when his suffering was indeed terrible. Dr. W. H. Myers, surgeon to above institution, after an examination with the sound, pronounced the case one of multiple calculi, and advised an early operation.

On June 23, 1884, the patient was anæsthetized, and the surgeon, assisted by his son, Dr. Herschel Myers, and in the presence of the leading physicians and surgeons of the city, proceeded to perform lateral lithotomy. The viscus was entered easily, and the calculi, nine in number, were extracted. As many of them were sacculated, the extraction was performed with difficulty, The calculi ranged from the size of half a filbert to twice that size, all presenting one or more articular facets. The aggregate weight of the calculi was five and one-half ounces. The patient rallied well from the operation, and never presented an untoward symptom, on the 18th day was passing his urine per urethra, and now, on the 21st day, the external wound is almost closed, which is certainly a brilliant result in a patient of his age and condition incident to his previous suffering.

J. W. McCausland, M. D.

Fort Wayne, Ind.

News and Miscellany.

Good Advice to Medical Students.

At the opening of the summer session of the Cork Fever Hospital, Dr. T. B. Moriarty delivered an address to the students, from which we take the following:

"I fear an opening lecture of this kind would be considered incomplete if we did not give you some advice as to how you can best avoid catching fever. We have hitherto been so far fortunate that no student contracted contagious disease during the period of his attendance; and we can for this reason say to you, as we did to them, with greater confidence: Never try to beat up against time. Get up early and come here leisurely, after a good breakfast; and do not for any reason venture into the wards with an empty stomach, or in a heated condition, or at a time when your health is lowered by severe study or over-exertion. Remain in the wards as long as your duty only will require; and be careful when you are examining a patient not to inhale his breath; and also avoid dirty smells, observe extreme cleanliness, and wash your hands frequently. You have a right to expect from us, from the accidental position we occupy as your teachers, that we should bestow such an amount of time and attention as will enable you to thoroughly understand the nature and treatment of fevers; and if you carefully study the cases

you see here for a few months you will obtain a thorough knowledge of one class of disease, and this the most appalling which can afflict the human being; for the ravings of the fever-stricken cannot fail to excite your sympathies. We will have much to say at the bedside; and when we ask questions of the patient, we do so, first of all, for the sake of judging of his capacity; and, secondly, in order that you may yourselves be able to see how our inquiry is conducted as regards certain signs and symptoms of the various stages as we find them. In after-life, when you are thrown on your own resources, you will find this method useful in helping you to unfold the histories of the cases you have to treat. For this reason you will, I trust, endeavor to follow us in such inquiry, as this will form the groundwork of more certain knowledge. We have no need to proceed in haste, and least of all to try and make you believe we know more of febrile disease than any one else. Our position here is a twofold one—viz., that of teacher and student—but with a responsibility from which you are exempt. Let us hope that our language and our demeanor will be always as respectful to the poor patients here as it would be if they were in a position to call us in to see them in their own homes; public and private liberality, for which this city is so well known, gives them a temporary home here. Never forget that kindness and gentleness not only mark the man, but also bring their own measure of consolation to those who are ill. Success in life can alone be gained by a high sense of duty, always combined with self-regard and industry. The upright physician knows no difference in his province between the rich and the poor man. Ours is a humane and charitable work, and I am confident none of those I see before me to-day will ever lower this nobility of our profession, which is the hereditary right of all of us. The honor, dignity, and independence of this position are yours as much as mine, and if your conduct and respectful bearing will only equal those who have preceded you in your walks through this hospital, we can then rest in the assurance that this dignity will not be lowered by you. Let us then endeavor to rob death of its pain, and give consolation to all those who are placed under our care."

The Relation of Physician to Patient.

From an admirable address by Dr. John H. Galton (*Brit. Med. Jour.*, July 5, 1884), we extract the following:

From the patient's point of view, the duties of the physician are well summed up by old Burton, "Only thus much I would require, honesty in every physician." Often the all-important question arises, How far are we to be open in the expression of our opinion to the patient? Certainly so far as is necessary to his safety, or to the avoidance of risk. As to the name or nature of a disease, although absolutely frank in their statement to the friends, it is often merciful to withhold the exact nature of fatal disease from the patient. Are we in this matter to be wiser than Providence, which, knowing all, often discloses none? I would mention a case of cancer of the pharynx. A short time back, a case of congested throat, of some duration, disclosed, on closer examination, a mass of cancerous infiltration behind the tonsil. The patient was a strong-minded old man of 60, sturdy, gnarled, and stiff as an old oak; one would have thought him capable of bearing any definite knowledge better than uncertainty. I took a second opinion upon his case, which confirmed my own, and, on his return, he put the question directly to me, "Is it cancer?" I replied, "Yes." He rapidly made a will, and died in three weeks; whether or not the best termination, it is not in our power to say, but certainly the disease did not kill him, for there was neither hemorrhage, nor much ulceration, nor stoppage of food. There is one point upon which, perhaps, we are not sufficiently alive, and that is in promoting euthanasia, or dying in a pleasant way. When our cases fail to yield to remedies, we have to devote our efforts to relieve pain and distress; and I do not think that these should be slackened, and that we should be unaiding spectators in the last painful struggle of death. I have frequently found a quarter of a grain of morphia, given hypodermically, convert the prolonged agony of dying, most distressing to the patient and his friends, into a quiet gliding away. Hear what Bacon says upon this: "And, further, we esteem it the office of a physician to mitigate the pains and tortures of diseases, as well as to restore health; and this not only when such a mitigation, as of a dangerous symptom, may conduce to recovery; but also, when, there being no further hopes of recovery, it can only serve to make the passage out of life more calm and easy. For that complacency in death which Augustus Cæsar so much desired, is no small felicity. This was also observed in the death of Antoninus Pius, who seemed not so much to die as to fall into a deep and pleasing sleep. But the physicians of our time make scruple of attending patients after the disease is thought past cure, though, in my judgment, if they were not wanting to their own profession and to humanity itself, they should here give their attendance to improve their skill, and make the dying person depart with greater ease and tranquility." Our duties would be greatly lightened were patients in general to take to heart the advice of old Burton:

"1. That he be not too niggardly miserable of his purse, or think it too much he bestows upon himself, and, to save charges, endangers his health.

"2. That, out of bashfulness, he do not conceal his grief.

"3. A third thing required in a patient is confidence, to be of good cheer, and have sure hope that his physician can help him.

"4. That the patient is not too bold to practice upon himself without an approved physician's consent, or to try conclusions if he read a receipt in a book; for so many grossly mistake, and do themselves more harm than good."

Popular Cures for Disease.

The *Brit. Med. Jour.* says that a study of the history of medicine, especially in its earliest days, shows how quickly superstition found its way into the practice of the healing art: and, though modern science has almost entirely dissipated the

belief in amulets, charms, and talismans, the yearly pilgrimages of modern days to certain shrines show that some people still place more confidence in supernatural agency than in the prescriptions of doctors. In a recent paper, read before the Society of Antiquaries of Scotland, the Rev. Hugh Macmillan, of Greenock, drew attention to two boulders, having rain-filled cavities, on the shores of Loch Tay, which were formerly associated with the cure of disease. The first one is a large rough boulder of clay-slate, shaped somewhat like a chair. It stands in the middle of a field, and has a deep square cavity, evidently artificial, and capable of holding about two quarts of water. The rain-water contained in this cavity was believed to be a sovereign remedy for the measles, so that the boulder was known in the district as the "Stone of the Measles," and people came to it from all parts of the district, it having ceased to be frequented only in the lifetime of the present generation. The other stone is in the woods at Killin, and is called "The Well of the Whooping-cough," being formerly famous for curing that disease.

Lightning Strokes in France.

M. Cochery, the French Minister of Posts and Telegraphs, has presented to the French Academy of Sciences a report on the lightning strokes in France during the last half of 1883. The report gives the date, hour, and locality of the stroke, together with the number of persons or animals killed, and the nature of the damage and surroundings. During the month of July there were no less than 143 strokes, resulting in 13 deaths; in August, 9 strokes, with 6 deaths; in September, 14 strokes, with 4 deaths; in October, 1 stroke; and in November and December there are no strokes recorded. A survey of the two reports for the year 1883, which have been submitted by M. Cochery, leads to the conclusion that lightning strokes are, in general, more common during the beginning of the year than the end of it, and that they preponderate enormously during the summer months, especially June and July. The accidents have mostly occurred to persons who occupied a position near a tree, a chimney, or a house on an elevated site with trees around it; but there are cases of death in an open field and on a roadway. Several of the accidents have also been associated with the use of umbrellas. Several animals were killed by lightning strokes, of whose deaths no account is taken in this note.

The Disposal of Refuse in Large Towns.

About three years ago, the town Glasgow erected special works for the speedy despatch of the refuse collected all over the city. By the arrangements then adopted, the refuse is made to undergo a process of separation, by which it is made more valuable to farmers, and also of considerable profit to the town; for, by a process of burning, chemicals are extracted, and sold for a high price. The results obtained by this system have been so satisfactory, that the authorities decided to extend it; and recently there were formally opened additional works, which cover ground about an acre in extent. They are on exactly the same principle as the former, though, of course, with certain improvements that experience has suggested. The importance of these refuse despatch works, as well as their necessity, is brought out when it is remembered that, in the case of a city like Glasgow, there are 163 miles of roads and streets to clean and water, and from these 700 tons of stuff are gathered daily. To be able to dispose rapidly and profitably of such a large amount of waste material, speaks well for the system which Glasgow has adopted, and which as yet does not seem to have been taken up by any other large towns.

Subsoil Drainage by the Eucalyptus Globulus.

From a foreign exchange we learn that a curious instance of the power of the eucalyptus globulus to drain wide areas, and of the distance to which its roots will penetrate, is afforded by a story which comes from Alameda county. The owner of Bay Island Farm recently found a curious root-formation of the eucalyptus in the bottom of his well, about sixteen feet below the surface. The trees to which the roots belonged stood fifty feet from the well. Two shoots pierced through the brick wall of the well, and sending off millions of fibres, formed a dense mat that completely covered the bottom of the well. Most of these fibres were no larger than threads, and were so woven and intertwisted as to form a mat as impenetrable and strong as though regularly woven in a loom. The mat, when first taken out of the well, was water-soaked and covered with mud, and nearly all that a man could lift; but when dry, it was nearly as soft to touch as wool, and weighed only a few ounces.

The Paucity in Number of Medical Men in Russia.

That the Russian death-rate is the highest in Europe is attributed to the paucity of medical men in that country, combined with the habits of the rural population. Excepting the two capitals, where there are many German physicians, it is stated that there is no district in the empire sufficiently supplied with doctors. According to the latest returns, the average duration of life in Russia is only twenty-six years; of infants more than 60 per cent. die before they reach their fifth year; of 8,000,000, only 3,770,000 attain the age of military service—*i. e.*, their twenty-fifth year, and of these at least 1,000,000 are found, by reason of shortness of stature and weakness of body, unfit for military duties.

The Professor was Stumped.

"Gentlemen," said the professor to his medical students assembled in clinic, "I have often pointed out to you the remarkable tendency to consumption of those who play upon wind instruments. In this case now before us we have a well-marked development of lung disease, and I was not surprised to find, on questioning the patient, that he is a member of a brass band. Now, sir," continued the professor, addressing the consumptive, "will you please tell the gentlemen what instrument you play on?" "I blays der drum," said the sick man.

Teething.

Dr. K. Dehio, of St. Petersburg, has reported in the *Jahrbuch für Kinderheilkunde* a series of observations made as to the disturbances of infantile health which occur during teething, and the physiological development during that period, as evinced by the progressive increase which takes place in weight. The arguments he founds upon these observations are to the effect that such indispositions are not direct results of teething, but arise from the action of extraneous causes, to the influence of which infants are particularly susceptible at the time of dentition.

Items.

—In the *Lancet*, June 28, Dr. T. Edgar Underhill reports a case of fracture of three ribs from muscular action.

—In the *Lancet*, July 5, 1884, Mr. Bryant reports two cases of fracture and dislocation of the cervical spine, both fatal.

—The Honorary Degree of LL. D. was conferred on Dr. N. C. Husted, of New York city, by Syracuse University at its recent annual commencement.

—The true use of a porous plaster, according to a Milwaukee druggist, is "to retain the back in its proper place and let the pain crawl out through the holes."

—"Rough on Rats" has caused the death of another person, this time by suicide, the victim being a German shoemaker living in Newark, New Jersey.

—A special laboratory has been opened in the Pathological Institute, Munich, for the investigation of bacteria. Great things are expected to result from this step.

—The *Buffalo Medical and Surgical Journal* learns that a very advantageous piece of property has been acquired for a new building for the medical department of Niagara University, near the Grosvenor Library.

—The children of Indianapolis who were given twenty-five dollars' worth of pills stolen from a drug store, and ate them in mistake for candy, were lucky in one respect. The pills were of the homœopathic variety, and did no harm.

—Ophthalmologists will be interested to read some clinical observations on the use of jequirity in trachoma, by Dr. H. Knapp. His conclusions are that it is a quick, but not a safe remedy, and that at present its use ought to be restricted to cases of old and intractable pannus.

—A drama, called "Sister Grace," written by a doctor, and played for the benefit of the East London Hospital for Children, has just been presented at the Avenue Theatre, London. The play introduces hospital life and incidents. The binaural stethoscope made its first appearance on the stage.

—The celebrated alienist, Moreau de Tours, died July 2, at the age of 80. He was principally known by his psychological remarks on the effects of haschisch, and by his great work entitled *La Psychologie Morbide*, the ground-work of which is the celebrated paradox, which gave great offence at the time, "*Le Génie est une névrose.*"

—Sir Henry Thompson recently presented to the Museum of the Royal College of Surgeons his valuable collection of calculi, the result of 812 operations, both lithotomy and lithotrity.

—In the *London Medical Times*, July 5, 1884, Dr. Sidney Coupland reports a case of compression of bronchus by a "cured" aortic aneurism; collapse of lung; bronchiectasis leading to ulceration of pleura and pectoral abscess; death.

—Advices from the City of Mexico, by way of Galveston, state that on the 15th of July the fever was raging at Guaymas, and that there had been several cases at Mazatlan. It was added that as yet the disease had not appeared on the Gulf Coast this year.

—The Medico-Surgical Society, of Bologna, has offered two prizes of 500 lires each. First prize, Sgarze, for the best essay on The Surgical Treatment of Pulmonary Cavities. Second prize, Gajani, The Surgery of Diseases of the Stomach. The essays must be written in Italian, French, or Latin.

—Professor Bèclard, Dean of the Faculty of Medicine in Paris, has issued a circular to the professors, students and officials of the faculty, announcing that a list is open for the reception of the names of those who are desirous of joining the public subscription for a statue to the memory of the great chemist, J. B. Dumas.

—"I tell you, sir," said Dr. —— one morning to the village apothecary, "I tell you, sir, the *vox populi* should not—must not be regarded." "What, doctor!" exclaimed the apothecary, rubbing his hands. "You don't say that's broken out in town, too, has it? Lord help us! what unhealthy times these are!"

—The oil of white birch-bark (oleum betulæ), which gives to Russia leather its peculiar aromatic and lasting qualities, when dissolved in alcohol is said to be excellent for preserving and waterproofing fabrics. It renders them acid and insect proof, and does not destroy the pliability of the fabric.—*Chem. and Drugg.*

—In 1871 there were 300,000 deaths from cholera in Russia; in 1873 there were 16,000 deaths in Poland; in 1872–73 there were 140,000 deaths in Hungary; in 1872–73 there were nearly 27,000 deaths in Prussia; in 1865–67 there were 143,000 deaths in Italy. In Paris the mortality from cholera has been as follows: In 1832, 18,654 deaths; in 1849, 19,184; in 1853–54, 8,096; in 1865–66, 12,082; in 1873, 885. In England, in 1849, the deaths from cholera were 70,000. In 1817 the army of the Marquis of Hastings in India lost 9,000 men in twelve days from Asiatic cholera.

—A correspondent of the *Brit. Med. Jour.* relates the case of a man aged about 60, a publican and a heavy drinker, who had rather a severe cough; and, during a violent paroxysm, he felt and heard a crack in his left side, resembling, as he himself described it, the sound of a match when struck, this being followed by acute pain. Abundant crepitus was easily produced, on manipulation, over several of the lowest ribs, these having no doubt given way under the convulsive action of the diaphragm. The side was supported with plaster in the usual way, and he made an uninterrupted recovery.

Of Joliet, Ill.

(*Concluded from page* 119.)

THE STANDARD OF EDUCATION.

During the last twenty-five years, the standard of medical education has been elevated in a remarkable manner, and to an altitude undreamed of by educators twenty-five years ago. I need not specify the change in methods of teaching, or the changes in the sciences taught. It is enough to say that the difference in both, during the time mentioned, is greater than the likeness.

But there is still a cry for a still higher standard. We cannot regard the demand of those people who demand that the standard of education shall be so high that no man can get over it, or if a man does succeed, he shall come down on the other side a physical and mental wreck. That this is already the standard in some places is known to all, and instances of insanity and death from overwork among medical students, and persons trying to circumvent the diabolical inventions of the modern civil service inquisitorial commissions are also known to all. The fault of these things is very likely because the examiners have no correct conception of the nature of education, or of what an examination ought to be. Methods are ignored, and general laws in science ignored; but questions relating to special facts, which have no natural or mental relation to each other, and which educated men carry in their libraries, and not in their memories, are made the burden of these inquisitorial tormentors.

It is evident that the people who are demanding a higher medical education, mean an education of this character. What the teacher lacks in actual, verified, general science to teach, must be supplied by a year or two of cram, and this cram is made up by "storing the mind" with disconnected specialties in science, which the student must be prepared, by a strain of memory, to shoot off at the will or fancy of an examiner who, very likely, has recently copied them out of a text-book, and visits the text book again to compare the answers to the special conundrums.

Education is at its highest standard in medicine when enough special facts of each scientific subject are taught to illustrate the general law under which they are classed, and the proper relations are understood, and the methods by which these facts and others of similar character are understood. There is no more need of a medical practitioner remembering all the special facts in medicine and the allied sciences, and being able to carry the answers in his memory, than there is that a lover should know the definition of every word in Webster's unabridged, and be able to repeat a whole volume of a selection of household poetry when he pays court to his mistress.

A further fact to notice in the nature of education is that the teaching should be complete as far as it goes, and the truth being taught and learned that "verification is the test of scientific truth," those propositions only which are thus verified should be taught, the methods of verification fully understood, and the hypotheses, as a rule, given the go-by, except to refer to them as samples for

which no verification is yet discovered. Now, it may be said that "medicine" proper is not yet overburdened with verifications. The causal antecedents of most diseases are unknown; those which are known are easily learned and taught, and certainly those which are not known ought never to be made the subject matter of a student's examination to determine his qualifications in the divine art of healing.

In view of these facts, and in view of the physician's relations to his art and his living, all of which must be considered, I think the question practically considered, of what should be the standard of medical education, can be answered, and I will attempt it as follows:

The standard of education in medicine, of the nature and character that I have enumerated, must be high enough to enable the physician to compete with other physicians, and if other things are equal, to make a living by "practicing his profession."

It makes no difference what may be our æsthetic ideals of education and morals, and of the physical, mental, and moral nature of a man, our practical estimate of the standards of all must be based upon the laws of life and the methods of getting a living. There are no physiological or social phenomena, but when we analyze them down to bed-rock, bring us face to face with the "final design of the Creator," as well as the complete or not complete result of evolution; and we find that we cannot understand them or express them scientifically in any other terms than those given by the laws of life, and getting a living. The young man who visits his girl may or may not have the definition of every word in Webster's dictionary on his tongue's end, just as it is in the book, and may or may not be able to quote from his heart all the love selections from the poets, but he may secure his girl all the same, and this fundamental law of life is then fulfilled. And, as I observe it, the young or old doctor who attends a case of midwifery may or may not know or remember how to describe the "fœtal circulation" and the "blood relationship" of the placenta to the uterus, and yet the labor may terminate, not only with safety to the "old man," but with a happy mother and living child, and glory and pay to the doctor.

Another feature of medical education is the impossibility of educating all people to an equal standard. This fact is a corollary of the truth that all brains are not equal, or, at least, are not all alike; there are differences, especially relating to present methods of education, but whether these differences represent so many shades in degrees of excellence, is not so clear. I think the differences are quite as likely to represent shades of failure in the methods of education, and the knowledge of how to impart knowledge on the part of educators. I do not think that our most successful generals, scientists, ministers, doctors, lawyers, business men, inventors, or any other class of men, ranked so high in college examinations as those who were less successful after they left school and began the business of living and earning a living; and I am quite ready to declare that, measured by the practical laws of life, and what is required of a man to compete with his natural rivals in order to live, the result of an "examination" of his qualifications, as these examinations are usually conducted, whether by State boards, college faculties, or civil service inquisitions, is no possible criterion of the man's ability to make a living for himself and do his duty to his competitors at the same time—partly for the reason that education is too much a cram, and an examiner always goes on the principle that it is altogether a cram, and also acts on the principle that all men are alike, in memory, will, intellect, and emotion, as well as physical hardihood. The examiner, having only one rule of conduct, and the teacher having a single method and but one idea of the subject of teaching, will fail to adapt themselves to their students, quite as often, I think, as the students will fail to adapt themselves to them. The fact is that the most difficult mental feat on earth, or in the domain of mental activity, is to determine and judge of a man's ability to practice physic or make a living in any other way by asking him questions. Better wait and see. Colleges are driven by outside pressure into the cram methods of education. Prizes are yearly offered for superior excellence in special departments, and general scholarship, the superior excellence to be determined, of course, by examinations; and very often the prizes are all carried off by one or two students. The reason of this, it must begin to dawn upon the minds of prize-givers, is that though the prize-winners may have the formation of brain and mind which corresponds nearest to the teacher's methods, yet they do not always turn out the best educated and the best adapted to the real work of living and earning it by professional activities.

The teacher who can adapt himself to the different kinds of pupils, and their different mental faculties, will be most successful; and the examiner who can so adapt himself, is least to be pitied.

By the rules of prize-giving, I think it generally happens that the prize-winner is not the man who is best adapted or educated to make his way in the world, but he is best adapted to fill the requirements of an examination which taxes no faculty but memory of words, or special facts, which stands next to words; and I believe that when cram ceases to be the method of education, prize-giving will cease to be a custom; for it can never be a reward of industry so much as it is a reward of inheritance of superior mental ability—for the reason that all men are not born intellectually equal, and no industry can fill up the gulf between them.

From the tenor of remarks of the critics who wish to throw medical education into politics, one must conclude that these people not only suppose that all people are born intellectually equal, but must be educated by the same arbitrary methods, and examined by the same standards, and must be equal in their ability after school days to make a living. We find differences among people in all callings and all grades of life. Nations differ, races differ, people in the same occupations differ, people in the same townships differ, and people in the same families differ as greatly as any people. It is difference in people that makes society, and civilization, and social laws, possible and practical. These critics also think that the student must be graduated, or let out of a college, an old and experienced doctor. Education is a matter of a life-time. The song of the pessimist is that he no sooner learns to live than he must die. People are born helpless—they are not born giants, or athletes, or savants. Gestation has simply started the process of growth, and carried through to a great extent the process of differentiation of the ovum. Education is something similar in methods and intention. Education teaches or learns methods of growth, but the man must grow in the directions given him by his education all his life. The success of self-educated men, compared with college men, doubtless depends somewhat upon the faulty methods of colleges. But the critics are also prescribing methods for the colleges, and a notable requirement is the "preliminary examination," which has lately been imposed or adopted. I have little to say on this subject, for the reason that it is such a pet of the people who are not teachers in colleges, and are no longer students, in the college sense at least; but, perhaps most of them have learned their "preliminary education" since leaving college, and believe the need of it to be a long-felt want. The critics who prescribe this measure for colleges, generally preface their remarks by the "complaint" which I have quoted as the basis of this article. They say the profession is overcrowded, and therefore a "difficult literary preliminary examination" should be imposed as a method for colleges, and expressions generally follow this suggestion which lead us to expect that the measure will lessen the number of matriculants.

Now, a "difficult literary examination" must mean an examination in Greek and Latin, a prescription which will certainly be resented by teachers and students. In these days no rule of ethics or imposition of "health boards" can compel a man to study "classics" before being allowed to enter a medical college. A preliminary examination is, however, imposed by certain alleged educational authorities, and is adopted by many colleges; but to my mind the wisdom of the measure reaches no desirable end. It cannot be made to cover the classics, but can only cover reading, writing, and spelling, a little mathematics, and possibly a little physics. No one will or can gainsay that a preliminary education in science is a benefit to a man who enters a medical college, but I believe that a classical education is, if anything, an injury to him. The question of classical education is just now a hot one, and the probability is that it will grow hot enough to consume the wretched old superstition in educational methods. A scientific education helps a student in the allied sciences of medicine, because it is fundamental, and teaches by the method of verification as the test of propositions; and this method is of inestimable value to a medical student, and if he has learned scientific experimental methods, and has learned to reason inductively from verified facts to general laws, he has already learned what he must learn as a medical student, and this sort of a preliminary education is therefore all right, because it is not so very "previous" after all, but is a medical college method, learned by the student before he enters college.

The selection or rejection of students for this reason, however, is arbitrary and unjust. The Grecians were all athletes, and decided that for state reasons, and æsthetic reasons, no Greek should live who was not an athlete. Notwithstanding this rigid law, there were differences in the heroes of the Olympian games and in wars; though they were all brought up by the same trial of the "straight edge." The Greek made a political matter of it, and imposed a "preliminary examination" upon babies before they were allowed to enter childhood, or have their swaddling clothes. If the political commission de-

cided, after their examination, that the child might grow up an athlete, and do honor to the profession and the æsthetic taste of the Spartan idea of things, then the child lived; if not, then the child failed to be an athlete very early in life; and yet, many Spartans failed to become Olympian heroes.

It is notorious that preliminary or literary degrees are scarce among physicians. There appears to be no natural connection between literary study and professional excellence. I am acquainted with a graduate of a literary college, who was even tutor in Greek in his college, and who speaks German and French fluently, and yet is not successful, professionally, in any distinguished manner; and I know another physician who is wealthy for a doctor, and made his own property, who has a large surgical practice, and who cannot solve a problem having fractions, or state a rule of grammar, and who, in making out official papers as surgeon of a railroad, spelled Kansas with two C's.

I mention these cases as samples of two kinds of doctors; and I am willing to admit that the classical education of one adds to the "dignity of the profession," but I claim that the illiteracy of the other does not appear to hurt his practice, or inhibit his capability of making a living.

THROWING PHYSIC TO THE DOGS.

By this caption I mean turning the matter of medical education over to politicians as the remedy for overcrowding.

Medical societies in some States are making strenuous efforts to divorce medical teaching and license-granting. It appears by bills introduced into legislatures that these men propose to license physicians by political methods instead of educational methods. The political machine is to appoint a board, whose duty it shall be to examine all candidates from colleges for diplomas; and if any diplomas are to be granted, the State will decide who are qualified to hold them.

Now, provided this thing could be run as these projectors imagine, let us look first at the unfair discrimination. It is supposed, of course, that old and young doctors, who are qualified by diplomas when the law goes into effect, will not be subject to an examination by this board; but the man who is later in the field must submit to this discrimination by the State. Obviously the *animus* of this proposed law is that the profession is overcrowded, and politics will not favor the young brood to the extent that the teachers will. The projectors of this law are no less foolish than wicked. They have no right to impose greater restrictions upon others than were imposed upon them; for all men in civilized countries have equal rights to make a living as pleases them best, while the political methods of obtaining diplomas are so different and so easy compared with the educational methods, that the foolishness of this proposed law must be apparent to any person who has any experience with political methods.

This law, in part, is already in effect in Illinois, and has been a working factor of the Board of Health for several years. The law gives the Board power to grant licenses to persons independently of educational methods. The Board does not teach medicine, it simply examines. The result is that many students have been taken out of colleges, who were in the first or second year of study, and granted license by the State, by virtue of a "certificate of examination." It is a pity that the teachers in colleges have not discrimination to know that one student may learn as much in six months as another in three years; but when the State says this is a fact who can dispute it?

On the other hand some 1,700 "doctors," who had not diplomas, and who were afraid of the examination, or were refused examination, left the State—so it is claimed. Again, not a few druggists who had prescribed over the counter for ten years previous to the law, were licensed as physicians by the Board: and why shouldn't they be? for the political machine this year appointed a druggist—no doubt a very able druggist and politician—to be a member of the State Board which regulates medical education and practice and preventive medicine through the State.

It is generally conceded that reform in public social institutions depends upon their being taken out of the political machine. The public schools are trying to get loose from politics. The insane asylums are making a similar effort. In this country reform in any public abuse means that politics has let go.

Why should other colleges, Greek and Latin schools, not be subject to politics? Perhaps it will be the last resort of the adherents of the classics to throw these colleges into politics. While the fashion is rampant, why should politics not control the theological and law schools? Theology would like closer relations to the State, and no doubt lawyers could engineer the politics of the State so as to make their graduating briefs even briefer than they are. It is apparent that not a few of the medical men who are, if not many who are to be, need the protection of the State, but the protection should be given by an asylum for the feeble-minded.

When this law goes into effect, the State Board of Examiners will be appointed, of course, by the political authorities, and will be a wheel in the political machine. Its methods will be political methods. Of course their qualifications will be political, for who would be competent to examine them? The Board will represent one political party, and perhaps three persuasions in medicine. To pass such a Board, by examination, will require greater flexibility in the minds of the candidates than the text of Holy Writ; and it must be admitted that there can be found no evidence that when a medical student goes before this Board for examination, the Board is more qualified to examine the student than the student is to examine the Board.

Separation of the teaching power, and licensing power, will soon do away with teaching power, nearly or quite, because the methods of obtaining diplomas will be political methods—and can any of the gentlemen who are striving to bring this law about imagine that such measures will lessen the overcrowding of doctors? The educational methods of getting medical diplomas are well known, but let us compare these methods with what will be the method in politics. Judging by the record in Illinois, if the applicant for license has political influence, and has attended one term in a medical college, he will be made happy by the receipt of his political license to practice medicine.

THE TRUE RELATION OF GOVERNMENT TO INDIVIDUALS.

All people will do what they can to qualify themselves to make a living; but very often the duty of all these people to others must be under the controlling power to shape their conduct so that each can have an equal chance. Manifestly there is a sharp line of demarcation, which separates personal liberty from the control of government. The judiciary and civil officers interfere to prevent or punish crimes of people against each other; but if a man wants to open a grocery store in a town which is already overcrowded with grocery stores, he is not obliged to get permission from the judge, nor can other grocery-keepers get out an injunction to restrain him, nor would these grocery dealers even think of carrying the thing into politics.

Now, the case is like this in theology, law, medicine, or any other trade, occupation, or calling, by which a man tries to make an honest living. "Boards of Health" are necessary to take care of unlawful conduct among colleges and doctors—those who buy or sell diplomas, or practice without diplomas; but a Board has no more business with a doctor who has a diploma, or with a college which is up to a required standard, than the sheriff has to do with a man who buys a horse, and pays the contract price.

Ministers do not ask for political control in education or faith. Lawyers would certainly never submit to an examination as to their qualifications by a board of politicians. Civil engineers consider themselves rather above political squabbles. Inventors never think of going into politics to prove their liberty or qualifications as inventors; and the fact is that the people of no profession or calling have ever stooped so low to conquer, or be conquered, as the medical profession, which is now trying to throw physic and physicians to the dogs.

RECURRENT IRITIS AND ITS RELATION TO CHOROIDAL DISEASE.

BY S. D. RISLEY, A. M., M. D.,
Of Philadelphia.

(*Concluded from page* 116.)

Notwithstanding these difficulties, Schnabel (*loc. cit.*) asserts that "the ophthalmoscopic examination of individuals suffering with acute iritis revealed, no matter what the cause might have been, most frequently diffuse retinitis." He appends a history of twenty-three cases of acute iritis thus examined. Five of the cases were diagnosticated as having both retinitis and hyalitis. With reference to this group of cases he states that: "The most remarkable fact demonstrated by the foregoing table is the *almost constant existence of retinitis with acute iritis*"—although he acknowledges that in the vascular system of the retina (in iritis), we do not see any remarkable changes. Among sixteen eyes having specific iritis, he found only one normal retina; and among ten having non-specific iritis, only three.

However strongly we may feel inclined to call in question the perfect accuracy of a diagnosis of diffuse retinitis, made through a muddy vitreous humor, particularly when there are no "remarkable vascular changes" to verify the retinal complication, still it must be acknowledged that it is comparatively rare to find an eye affected with acute iritis that has normal sharpness of sight, or in which the media are found transparent. The existence of opacities in the vitreous are, I think, by most men, accepted as evidence of the presence of choroiditis. Schnabel (*loc. cit.*), however, does not accept this dictum, but insists upon ophthalmoscopic verification of the choroidal disease for a diagnosis of its presence, and insists upon pri-

mary inflammation of the vitreous itself. In his study of twenty-three cases of acute iritis, therefore, he found "most frequently retinitis, comparatively seldom the presence of changes in the vitreous, and most rarely anomalies in the choroid."

The anatomical relations of the iris to the uveal tract, of which it is in fact an extension, would lead us *à priori* to anticipate a frequent connection between the diseases of the one and the other. Indeed it was hardly to be expected that an acute inflammation of the iris could be rigidly confined to that important structure, lying as it does in such close proximity to the ciliary body and muscle, enjoying the same bloody-supply. But it is equally probable that diseases affecting the choroid proper or ciliary region, might also, by the simple fact of continuity of tissue and blood-supply, attack the iris secondarily, or simply by a gradual process of extension forward. That such extensions of inflammation can and do occur has, I think, been demonstrated by the foregoing cases. It receives further confirmation in the following case, which will serve also to demonstrate the serious importance of this disease and the necessity for prompt and well-directed treatment.

There can be no question of the great importance of preventing the adhesion of the iris to the capsule, for however little influence the attachments themselves may have over the production of subsequent attacks of iritis, there can be no doubt as to their baneful influence when they by frequent repetition finally lead to exclusion of the pupil; this will be painfully illustrated in the history of Case 3. I have already presented to the Society the early history of this case, as one of a group illustrating the history of secondary glaucoma. I now repeat it more in detail with the subsequent development:

Case 3. Mrs. D., æt. 46 years, consulted me August 17, 1881, her vision being so seriously at fault that she was led into the consulting-room by her husband. She gave the following history: Her first eye trouble was experienced in March, 1880, when she quite accidentally discovered that vision in O. D. was impaired. The impairment steadily progressed without pain or other symptoms until the following July, when she was attacked with violent pain in the right eye, which spread over the entire right side of the head. The eye was red, tender to the touch, photophobia so intense, and pain so severe, that for eight days she was forced to remain in bed in a dark room. Her attendant was a homœopathist.

The impairment of vision increased rapidly after this attack; there were frequent subacute exacerbations which simply added to her constant discomfort, and were characterized by an increased dimness of vision, exaggerated tenderness, and injection of the ball. The left eye had given no signs of trouble until April, 1881, about one year from commencement of impaired vision in the right. She then noticed diminished acuteness of vision, which steadily progressed up to the present time, but with no evident onset of inflammation. It had had, however, frequent attacks of redness, attended with periorbital pain, dread of light, soreness of the ball, etc. Mrs. D. to all appearances was in perfect health; she had married late in life, and had enjoyed uninterrupted health; had never been pregnant: the menstrual function had been regularly and painlessly performed until the present month, which she had missed for the first time, and was now annoyed by alternating flashes of heat and perspiration.

In O. D.: T+2, cornea steamy, and sensibility markedly diminished, some ciliary injection, anterior chamber shallow. The iris was atrophic and fixed; pupil 2 mm. in diameter, and occupied by a grayish-white web, and papillary margin of iris attached in annular synechia: only grayish-red light from fundus; there was no pouching of the iris; counts fingers only with difficulty and as shadows, the hand being held between the eye and source of light. Field taken with candles shows perception in temporal field only.

O. S.: Cornea also steamy, sensibility somewhat diminished, some ciliary injection, anterior chamber shallow, iris discolored, nearly annular synechiæ, no pouching, T + ? F. perfect, V=$\frac{2}{CC.}$ Solution of eserine sulphate, 1 gr. f℥j., relieved somewhat the periorbital neuralgia, and the steaminess of the cornea diminished, but there was no improvement in the vision.

On August 31, I did a broad iridectomy upward on the left side, and a large sclerotomy on the right, in the hope of diminishing the tension and relieving the pain, as I had no hope of restoring useful sight in the right eye. The iridectomized eye recovered slowly and with considerable reaction, while the right recovered from the sclerotomy without any reaction, and with entire relief of pain. Three weeks after the operation, O. D. white. T. *n;* free from pain; cornea transparent; pupil as before; anterior chamber normal; but much to my surprise V had risen to $\frac{20}{CXXVI}$ and the field now taken on perimeter had extended in all directions. O. S. showed typical coloboma: anterior chamber normal; T.—; V, quantitative

perception; cornea transparent; V steadily improved in both, so that three months after operation, during which she had steadily used the weak eserine sólution, O. D. $V=\frac{20}{L\,X\,IV}$. O. S. $\frac{2}{C}$, and she visited the office without a guide.

The improvement continued until, notwithstanding occasional attacks of redness, the following September, 1882, one year from the date of operation, when there began an insidious onset of serous iritis in the sclerotomized eye, with punctate deposits on Descemet's membrane and pouching of the iris without increase of tension, and V sunk to $\frac{15}{CC}$.

O. S. as before. On September 26 I did a broad iridectomy in O. D. upward, leaving a faultless coloboma, and liberating a quantity of yellowish glutinous fluid from the posterior chamber. The eye recovered with but little reaction, and all went well until the night following the fourth day of the operation, when she was awakened by an acute pain in the eye. The following day the anterior chamber was filled with blood. The clot slowly absorbed, the eye softened, and she gradually lost all perception of light. In a few months deposits appeared in Descemet's membrane in O. S. and without pain, V steadily failed until only merest quantitative perception remained.

During these months she suffered much from the troubles associated with the menopause, which doubtless had to do with the unfortunate termination to a most interesting pathological history.

The case furnishes wide scope for speculation regarding its pathogeny. Her failing vision at the outset was surely not iritis, but some disease of the deeper tunics, most probably retine choroiditis. The following violent attack of iritis, resulting in adhesion of the iris to the capsule, the subsequent subacute exacerbations, with the formation of additional bands of lymph, until exclusion of the pupil was reached; then the appearance of secondary glaucoma, with the increased tension of the ball, the cupping optic nerve, the contracted field of sight and almost total blindness; the rapid relief of all the symptoms, by simply incising the angle of the anterior chamber, to be followed by widening of the field and a large restoration of sight, notwithstanding the fact that the gray film still covered the pupil and the iritic adhesions remained: furnishes a picture of disease that cannot fail to interest, although in many respects it baffles a satisfactory explanation. Had the early treatment been so conducted as to prevent the formation of the synechia, until such time as the primary inflammation of the deeper tissues should subside, there is no question but that the ultimate result would have been very different. For in that case the secondary glaucoma would doubtless have been omitted from the picture of disease.

In O. S. the synechia was not annular, so that there was still some small communication between the posterior and anterior chambers. The result of the iridectomy in this eye was disappointing, as compared to the brilliant, though unexpected, but unfortunately temporary, result in the right eye.

The rapid improvement in O. D. can probably be explained by the relief of the glaucomatous tension afforded by the sclerotomy. Notwithstanding this, the choroidal disease slowly progressed toward a fatal issue. It is to be regretted that iridectomy had not been done instead of sclerotomy. The only excuse was that the eye was regarded as hopelessly blind, and the operation was designed to relieve the suffering of the patient.

In the light of comparatively recent investigations, the progress of the disease from the right to the left in the first instance, and the onset of serous iritis about three months after the loss of O. D., furnishes a very interesting history in the light of recent investigation into the pathology of sympathetic irritation.

If in these remarks I have succeeded in making clear that iritis is more than an inflammation of that delicate membrane, I shall feel that I have accomplished my purpose. I do not wish to assert that all cases of iritis begin in the choroid and ciliary organs, but do assert that many exist only in common with inflammation involving the deeper structures, and that their treatment, therefore, should be conducted with this fact in view.

There are many cases in which no evidence of inflammation of the retina or choroid can be gained as having preceded the attack of iritis, where, nevertheless, after the subsidence of the iritis, the deeper trouble was revealed. That both may have been due to a common cause, or that the trouble simply extended backward by virtue of anatomical relations, cannot be denied. But that even in simple idopathic iritis, attacking the iris primarily, there is also profound congestion of the entire choroidal tract, is unquestionably true, and it would be folly to deny that this congestion might, under favoring conditions, *e. g.*, existing dyscrasia, pass over into a pathological state, involving both choroid and retina.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL COLLEGE OF MEDICINE, LOUISVILLE, KY.

BY DUDLEY S. REYNOLDS, M. D.,

Professor of General Pathology and Diseases of the Eye and Ear.

(Reported by Allen Kelch, M. D.)

Impaired Sight as a Ground for Pension.

Gentlemen: As I have frequently had occasion to examine claimants for pension on account of injuries or diseases alleged to have occurred in the course of military or naval service, I have requested two recent applicants to come to the clinic to-day, inasmuch as both of them illustrate important points to be considered both in the determination of the liability of the government and the precise nature and extent of the disability. Grave responsibilities devolve upon those who are called upon to examine applicants for pension, and I believe the two cases I shall present to your consideration to-day are especially worthy of your careful study.

The first case I shall present is Mr. F——. He is an Irishman, simple in manner, and apparently honest in purpose. The first time I ever saw him he was suffering from ulceration of the cornea, and from an aggravated form of the disease which you now see affecting the margins of his eyelids, a parasitic affection of the hair-follicles, denominated *tinea tarsi*. Like Leah, the daughter of Isaac, he has lost all the lashes from the left upper lid, and the greater portion of those from the right. He is blear-eyed, in that he has lost the lashes, and that the margins of the lids are swollen, red, and ugly. When Jacob had labored seven years for Rachel, he was given Leah because she was blear-eyed and ugly. Ophthalmic medicine in that day was evidently not so well understood as it is at present, and it may not be inappropriate to add that it was not as well understood in 1867, when I first saw this man, as it is to-day. You observe that he squints; that the left eye appears smaller than the right; that the left eye is now of no particular use, because the extensive opacities of the cornea existing in former years obscured the vision by preventing the entrance of light; and the eye being of no use, has accordingly become convergent. In the right, corneal ulceration has at times appeared, but fortunately it has never extended so deeply as to involve the proper substance of the cornea. Consequently, vision equals $\frac{20}{40}$ in this eye, and he is able to read the lines in his prayer-book, though he says he cannot read the newspapers. Although I have known this man since October, 1867, I never knew until a few days ago that he is a claimant for a pension. I have certified to my knowledge of his afflictions from the date of my first service to him to the present. He says he was a soldier in the late war, and that in 1863 his regiment was marched into Louisville to take charge of the provisions which were stored in the warehouses along the river front, and piled up in great heaps upon the levee covered with tarpaulins. He says he was accustomed to go home regularly when off duty, and that when he heard that General Bragg was coming into Louisville, he rushed home and told his family to seek a place of safety; and returning to his post of duty, remained there day and night without food, guarding the government's provisions. He says he looked so long and anxiously for General Buell to come and give him relief that he strained his eyes, and they have been sore more or less ever since. He now concludes the government ought to pay him a pension for the sacrifice of his vision.

The question arises, ought the military service, with its exposures and vicissitudes, be held fairly accountable for the damage to Mr. F.'s vision? Surely the *tinea tarsi* was not contracted through the fault of the government, although it is true the long-continued exposure in doing guard duty, with insufficient rations, may have debilitated his system and crippled his nutritive functions so as to have laid the foundation for this mischief. It is, therefore, a matter of responsibility and extraordinary difficulty to determine how far the government is liable. Leaving that, however, to the authorities in the Department of the Interior at Washington, I have been obliged to say to what extent this man is incapacitated from performing manual labor. He tells me his occupation is that of a stone-cutter; that he can no longer see the lines upon the stone, and that he has never been able to do so since the war; that he could never dress the stone such as is used for curbing the sidewalks in our streets, and that he is obliged to depend upon common labor, the reward for which is not more than one-fourth that allowed to a stone-cutter.

It would therefore appear that this man should be allowed three-fourths the government rating in the pension allowances, as he is by his affliction deprived of the power of earning more than one-fourth at manual labor what he formerly earned at cutting stone.

The next case I have to present is that of J. M., 44 years of age, tall, well-built, and of good address. He claims relationship with some of the most distinguished families in the country. He says he was a non-commissioned officer in the United States army in the volunteer service, and that in the forced marches the great fatigue to which he was subjected during the military campaigns in the South, his sight failed him. He is, in consequence, now an applicant for a pension. By reference to my notes, I find that my first acquaintance with this man began in 1872, when he called to be examined as to the state of his vision, and for me to note the extent of its impairment. I then made affidavit as to his condition, and took notes of his case. Whether this ever went to Washington to the Pension Bureau I am not able to say. He comes now, however, for the third time—this time in obedience to an order from the Commissioner of Pensions, who has sent him to me for examination as an expert. This time I am requested to make a particular kind of examination, with the view of determining not only the nature and extent of the impairment of vision, but the probable cause of the disease which gave rise to it.

He is a man well-nourished; he has white scars in the arches of the soft palate, particularly upon

the right side near the base of the uvula; he is deaf in one ear; the iris in the left eye has been inflamed, and the pupil is now adherent at two points, viz., below, and at the temporal margin. These attachments of the iris to the capsule of the lens have no other significance than that the iris has been at some previous time inflamed. With this eye he is able to count fingers only at ten inches. Ophthalmoscopic examination shows floating bodies in the vitreous chamber. It shows a creamy-white colored disc, with very small arteries and very small veins, the arteries being so small as to require very careful examination to find them. The marginal outlines of the optic disc in this eye are somewhat irregular, and are imperceptibly shaded off into the surrounding structures.

The right eye is differently affected; the pupil, as you see, is quite widely and uniformly dilated; particles of dark pigment adhere to the anterior capsule of the lens, which shows that there has, at some time previously, been attachments of the uveal substance of the posterior surface of the iris; in fact, he has had inflammation of the iris in this eye, though less severely than in the other. In this eye, as in its fellow, floating bodies appear in the vitreous which appear to be shreds of lymph, with here and there the remains of contracted blood-clot. The marginal outlines of the the optic disc in this eye are difficult to trace. The extent of cicatricial tissue is greater here than in the other eye. A singular condition, however, is observed. One branch of the arteria centralis retinæ passing upward and toward the temporal side sends out a pair of twigs which surrounds the region of the macula lutea, and a single vein just below the horizontal line appears in the disc.

It would seem that the plastic effusion surrounding all the other branches of the arteria centralis and all the corresponding veins had been sufficient to produce closure in the vessels whilst this one twig alone remains to carry the blood-current. His vision in this eye equals $\frac{2}{70}$, with an extremely limited field of vision, covering an area of but fifteen degrees from the forea centralis toward the temporal side and ten degrees toward the nasal side, with a fraction less than ten degrees above and below. The register of his field of vision which I have drawn diagramatically upon the blackboard was obtained by the use of Risley's perimeter, and is, therefore, exact.

Yesterday I was called upon by an agent of the Pension Department, who sought my deposition in this man's case. After I had completed this description which I have just given you, except that it was more in detail, I was asked for an opinion as to the cause. Without hesitation, I answered, "syphilis." He had had evidently what is described as gumma developed in the connective tissue investments of the optic nerve. This had existed in both eyes, extending over the whole surface of the disc in the left eye and covering all except the temporal side, corresponding to about $\frac{1}{3}$ of the whole disc; the invaded part representing in form a triangle, the base of which corresponded to the temporal margin of the optic disc, whilst the apex seemed to lie directly in front of the porous opticus. This fortunate limitation of the disease enabled me to determine at once the nature and character of the pre-existing inflammation. No other disease which yields to the action of drugs ever shows that distinctly circumscribed character, and at the same time destructive inflammatory action. Syphilis alone appears as a distinctly circumscribed plastic inflammation in non-vascular structures and in connective tissue investments of nerves.

I had occasion at the meeting of the Kentucky State Medical Society at Lexington in 1880 to point out some interesting observations upon circumscribed cortical inflammation of the optic nerve. I had for some years prior to that date been collecting notes of cases of this singular manifestation of syphilis. The publication of that paper brought, through the influence of many professional friends, a large number of other cases of this form of disease. Yet I am impressed with the idea that the profession in general has not given due consideration to this subject. If it can be made to appear that the United States Government is responsible for the ravages of syphilis contracted by its soldiers, this man surely deserves a pension. If it should appear, however, that the Government does not assume responsibility for the effects of syphilis contracted in the military service, then this unfortunate man is doomed to disappointment.

Claimants for pensions are an interesting class of people, and a great many curious cases appear in the course of the duties of an expert, whose services are occasionally sought by the department in the cases of those who base their claims upon damage done to the eyes or to the ears. A few days ago a man receiving a pension upon the rating of one-fourth disability came from a distant mountain region by direction of the authorities at Washington to have me determine the nature and extent of impairment of sight, with special instructions to observe with great care the precise condition of each of the tunics of the eye and particularly the condition of the optic nerve and the retinæ with reference to probable atrophy of the nerve as a consequence of typhoid fever, the man having perception of light only.

The lids were adherent to the eyeballs nearly to the cornea-scleral junction, whilst the corneæ were rough, vascular, and so densely opaque as to make it impossible under the most favorable illumination to see any part of the iris. It was not difficult from the history given by the man to determine that he had had acute conjunctivitis during the military service, and that the regimental surgeon by making applications of caustic daily had destroyed the conjunctiva as well as the surface of the cornea.

In that part of my certificate which required the extent of his disability to be rated according to his incapacity to earn a livelihood by manual labor, I took occasion to say that the disability was such as to entitle the applicant to all the government allows a soldier who has lost both eyes.

Another very interesting case referred to me with a letter of instruction to examine particularly the tunics of the eye, and to determine the question of any impairment of vision I might find, and the probable cause of it, with special directions to be careful in rating the extent of his disability, was the subject of a recent examination. He had been a pilot in the naval service; he is

about 62 years of age; for twenty years he had suffered impairment of sight, which was equal to $\frac{20}{70}$ with the aid of the glasses he wore; without these he saw $\frac{20}{200}$.

Ophthalmoscopic examination revealed nothing abnormal, except opaque striæ in the left lens; oblique illumination showed slight haziness in the central portion of the right lens. Suspending his accommodation, which would appear unnecessary in a man of his age were it not for the suspicion he might have astigmatism, and subjecting him to the test, I was able to bring his vision to $\frac{20}{30}$ in the right eye, and to $\frac{20}{40}$ in the left. It became at once apparent that abnormal refraction of the eye, due to a malformation of the cornea, was the cause of his trouble, and, as is usual in such cases, about the age of forty he began to experience difficulty in reading at night, and was not able to see the finest type either by day or by night. At the age of forty-five he experienced difficulty in following his profession as a pilot, and this difficulty increased as years rolled on; and the man honestly no doubt believed himself entitled to a pension, and not entirely without apparent reason, charged the long vigils to which he was subjected in the naval service of the United States with the impairment of his sight, which, of course, became more manifest with physical fatigue and advancing years.

The want of perfect perception under correction of the error of refraction is evidently due to the incipient cataract, which it is unreasonable to suppose has been present for twenty years, or even twenty months. It is believed, from the presence of central and slight opacity of the lens, that senile cataract is beginning to develop. The opaque striæ in the capsule alone may have existed for a long time, but their polar position makes this improbable.

I hope these few citations from my experience may serve to put you on your guard in your examinations of applicants for pensions, and make you think more deeply than it appears pension examiners are in the habit of doing before certifying to the extent and probable cause of disability from impairment of sight.

Opacities of the cornea are sometimes so slight as to escape detection unless artificial illumination is resorted to, and yet so great a hindrance to the passage of light into the eye as seriously to impair the sight. You may sometimes be able to decide from the form and position of the opaque spot in the cornea as to its probable cause. For example, a man referred to me once for examination with the view of determining the amount of impairment of sight from an attack of small pox contracted in the army, had near the central portion of the cornea distinctly circumscribed circular opaque spots. I consequently gave it as my opinion that this could have resulted from an attack of variola. Had the opacity been of the nature observed in F.'s case, of irregular outline, and In the form of spear-like points projecting from the margin of the cornea toward its centre, with an irregular and dense opacity in the central part, I should have said that some other cause than that of variola alone had been operating here.

The eruptions of variola are symmetrical and always round. They are always distinctly circumscribed; consequently the remaining opacity, especially in the cornea, will exhibit this symmetrical circular form. Suppurative inflammation of the cornea might follow an attack of variola, and give rise to dense opacities like those in F.'s eyes. In that case we should say that some other cause than that of variola had been present and operating. In the case of Mr. M., the circumscribed portion of sound nerve structure in the right eye remained too distinct to admit of mistake; and the circumscribed character of the destructive inflammatory action which had been present in all the remaining portions of the end of the nerve, with the fluid state of the vitreous humor in both eyes and the floating bodies, and this peculiar state of the end of the nerve in the right eye, fixed it in my mind as being absolutely certain that he had syphilis. The character of the cicatrices at the base of the uvula and the right side of the soft palate, the impaired hearing in the right ear, all pointed to the syphilitic character of the iritis, which too was evidently of circumscribed character and limited extent in the left eye, as near the temporal and inferior margins of the pupil it became adherent to the capsule of the lens.

I did not inquire for the history of this man's affections, because I saw the characteristic signs of this specific form of disease with which he suffered, and because, further, I have long since learned to attach but little importance to the history of the case furnished by the patient or by the friends; and more especially in such cases as this, where the personal interests would naturally tend to bias the judgment, and lead the patient and friends to attempt the concealment of the real nature of the disease.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Discussion on Recurrent Iritis. (*See pages* 116–145.)

Dr. Shakespeare, in opening the discussion said: "I agree with Dr. Risley as to the importance of a knowledge of the pathology of these troubles, but I am not entirely in accord with him when he suggests that recurrent iritis is most frequently the direct consequent of extension of inflammation from the choroid.

"My own observation, and even some of the cases related by Dr. Risley, create in my mind the very strong impression that recurrent iritis, when not directly caused by irritation due to suddenly and constantly checked movements of the iris, where a partial synechia exists, is frequently brought about by constitutional conditions which affect the iris quite as directly as they do the choroid. I refer, for instance, to the agency of the syphilitic or the rheumatismal poison in the production of inflammations, and express my belief that when recurrent iritis is not the direct result of the combined irritation of posterior synechia and of a disturbance so slight or transient as in itself to be usually incapable of exciting deep inflammation, it is very often induced by the action upon the iris of a specific irritant, such as the virus, whatever that may be, of syphilis or rheumatism. I can see no valid reason for assuming that recurrent iritis and choroiditis, when as-

sociated or single, and occurring in a rheumatic, gouty, or syphilitic patient, are not each caused by the same constitutional irritant.

"I by no means deny that there are cases of recurrent iritis, where the inflammation of the iris appears to be an extension of an acute, or of an exacerbation of a chronic inflammation of the deeper portions of the uveal tract.

"But Dr. Risley seems to be of the opinion that such is the customary origin of recurrent iritis. It is on this point, then, that I differ from him. Moreover, the author, reasoning from his view of the usual course of recurrent iritis, arrives at the conclusion that adhesions of the pupillary margin of the iris and the adjoining capsule of the lens, so long as the whole pupillary border of the iris is not bound down, and the communication of the anterior and posterior chambers of the eye thus closed, are comparatively insignificant matters, and should ordinarily occasion little or no apprehension. Here again I must differ from him, and still more positively than before.

"I regard it as all-important in the treatment of primary iritis to guard most carefully against the formation of posterior synechia. Furthermore, I consider it important, after the second attack has established the recurrent nature of the malady, and at a favorable moment, to carefully separate the synechiæ if they are not too extensive, or, in the latter case, to remove a portion of the iris by iridectomy.

"Recurrent iritis after synechia is sure in time to bring about complete occlusion of the pupil—a condition which, unless remedied by operation, is certain to prove most disastrous. In order to remove the constant irritation of the iris, caused by one or more bonds of adhesion to the lens, and, still more important, to remove as far as possible the risk of subsequent complete occlusion of the pupil, I do not hesitate to advise the separation, at a proper moment, of slight adhesions, or the performance of an iridectomy if they are very extensive.

"I am very well aware that occasionally (rarely indeed) the capsule of the crystalline lens, at the point of attachment, may be torn in the effort to detach the synechiæ, and a traumatic cataract be established. But the danger is, I think, so small in comparison to the danger that the eye may be ultimately destroyed if the synechiæ be left to themselves, that it is, as a rule, safer to follow the practice of removing synechiæ when recurrent iritis is once confirmed. Of course, the presence of a constitutional irritant greatly complicates this problem. In the cases, which I believe are comparatively rare, of recurrent iritis by extension of inflammation from the choroid or ciliary body, it is possible that the best procedure would be to let posterior synechiæ alone so long as they are not complete, and do not occlude the pupil."

Dr. Little: "Dr. Risley's paper is very important and suggestive, for the early recognition of iritis and its proper treatment prevent or mitigate the serious results that follow in eyes thus affected.

"The vascular tissues of the eye, composed of choroid, ciliary body, and iris, are to be considered as one, and to say that inflammation is limited to only one part of it is difficult.

"The treatment is largely mechanical, that is, the whole tissue when inflamed should be made free from muscular action; the iris dilated so no adhesions occur; the ciliary muscle and choroid likewise passive, so as not to damage the retina or vitreous; after subsidence of the inflammatory processes, if optical defects exist they should be corrected, so as to prevent recurrent attacks from irritation and congestion that exist in the tissue when optical defects exist, for the effort at seeing produces trouble in these cases, and gives a foothold in a congested tissue for the constitutional taint, specific, rheumatic, or otherwise; mere exposure will produce the same result. The constitutional treatment is more effective in eyes free from strain and normally vascularized.

"As to the use of eserine in iritis, while a few years ago it was considered courageous to use it, in certain cases it acts well, care being taken to guard against adhesion by using atropia at stated times to prevent its adhesion; in cases where the adhesion already exists, it works well in relieving pain; but in the average case of iritis, atropia must be looked upon as the only treatment locally.

"Dr. Risley's suggestion and good effect he had with eserine in a case of sympathetic iritis, while suggestive and contributory to advance in therapeutics of this disease, cannot yet be looked upon as a preventive of sympathetic inflammation of the eye, any more than eserine can be claimed as a permanent method of cure for glaucoma by its use.

"The presence of hyalitis in these severe cases of iritis, presenting a view of the fundus of the eye, can be helped or cleared up to some extent by the use of electricity, so that changes in the retina or choroid can be recognized.

"Opinions as to operative procedure differ in these severe types of iritis; it is better to wait till severe symptoms subside or disappear, and yet some cases do well by immediate operation; not enough such cases have been reported in comparison with those that have had no operation, for any judgment or statistics to be grounded; personal experience gives different opinions to observers."

Dr. L. Webster Fox: "I rise to give the clinical history of a case of recurrent iritis, ending in sympathetic ophthalmia. Eighteen months ago I was asked, in consultation, to see a patient who had had several attacks of iritis in the right eye.

"Mrs. E., aged thirty-three, married, well developed, with an irrelevant family history, always enjoyed good health and normal vision. The family physician three months previously was called to see the patient, who was suffering with pain in the eye-ball, accompanied by supra- and infra-orbital pain, a marked ciliary zone of congested blood-vessels, a discolored iris which was sluggish, and vision blurred. Atropia solution, grs. iv. to ℥j., one drop every two hours, and internal medication of calomel was given. The disease responded rapidly to the treatment; the eye regained its normal color with full acuity of vision; three weeks subsequently a second attack came on, which was again promptly treated with good results. Nine weeks after the second attack, a third was ushered in with very severe pain over the brow, down the track of the infra-

orbital nerve, congestion of the sclerotic vessels, with a deeper pink zone of ciliary blood-vessels, musty brown iris and hazy vitreous, with vision reduced to $\frac{20}{200}$; other than the hazy vitreous, no lesion in the fundus could be seen. The following treatment was instituted: Atropia sulph., grs. iv. to $\overline{3}$j., one drop in eye every three hours, internally; hydrarg. chlor. mit., grs. ij., guarded by pulv. opii, gr. $\frac{1}{2}$ twice daily, and four leeches to temple. The patient improved, and untoward symptoms passed off. The left eye was examined with the ophthalmoscope, and found normal, excepting slight degree of hypermetropic astigmatism. The eye (right) remained quiet for about two months, when another attack came on more virulent and aggravated in its symptoms. Upon instituting the atropia solution, it was found that posterior synechiæ had taken place, the pupil only responding to the mydriatic in the upper and outer quadrant, possibly to one-sixth its diameter. The media, which had regained its transparency, was hazy (vitreous), obscuring the details of fundus. The vision had fallen to counting fingers at eight feet. In addition to the calomel and opium, a mixture of hydrarg. bichlor., gr. $\frac{1}{48}$, pot. iod., gr. xx in water three times daily, was given; this treatment was continued till permanent salivation had taken place, which was in six to eight days; the hydrarg. was discontinued, but pot. iod. given as usual.

"In two weeks the inflammatory condition commenced to pass off, but vision was reduced to qualitative perception only, after the inflammatory conditions of the eye had disappeared (four weeks after the beginning of the last attack); the patient was suddenly taken with great pains in back of head and at times nausea; these pains became so intolerable that the patient had to be kept under the influence of a hypnotic for several days at a time, this condition lasting off and on for four weeks, at the end of which time paresis of rectus externus of right eye manifested itself; there was convergent strabismus with diplopia, but no hemiopia could be elicited; the patient at this time answered questions intelligently; a careful examination of the right eye revealed no change either in the irregular shape of the pupil or in the haziness of the vitreous. In the left eye, however, a marked change had taken place; owing to the condition of the patient, it was impossible to make an ophthalmoscopic examination of this eye for four weeks. Well-marked keratitis, possetates on Descemet's membrane, iris musty brown, vitreous slightly hazy (?), swelling of the optic nerve, arteries lessened in calibre, veins full but not tortuous, their reflex gone, several small spots of choroiditis scattered about the equator of the eye, the eye presenting a perfect picture of inflammation of the uveal tract. The urine was examined; no sugar nor albumen found. Medication was pushed till pronounced salivation and iodism made their appearance; notwithstanding this treatment, the eye (sympathizing) continued to grow worse until qualitative perception of light only remained (the paresis of the rectus muscle impressed). The vitreous became so filled with inflammatory products that it was impossible to make observations of the change that was going on in and about the optic nerve and choroid.

"The last attack of iritis in the left eye was four months ago, when the eye suddenly became painful and exceedingly sensitive to light, this attack lasting three days, the patient having been under constant medication (pot. iod.). Leeches to the temple seemed to relieve the extraordinary condition at once. The patient is still under observation, and at last examination the vision in right eye (primarily affected) was found to be $\frac{5}{200}$, at one time qualitative perception only; in left eye (sympathizing eye) qualitative perception only. I may state that this is the first case of sympathetic ophthalmia, due to recurrent iritis, that I have ever seen, although I had the opportunity of seeing many cases of recurrent iritis while clinical assistant and house surgeon at Moorfields Eye Hospital, London.

"Operative interference was the method adopted at the above-named institution, to protect the patient from recurrent attacks. This was done by excising part of the iris—Mr. Streatfield, at rare intervals performing this operation of separation of the synechiæ from the anterior capsule of the lens. The iridectomy was performed at such time when it was supposed that the iris was free from inflammation. An operation may be done with safety in from four to five months after the last attack of iritis."

Dr. Risley, closing the discussion, said: "I quite agree with Dr. Shakespeare in his estimate of the importance of systemic conditions in this disease. Not only are syphilitic disease, the rheumatic or gouty diatheses, frequent causes of idiopathic iritis, but they doubtless exert a marked influence in sustaining the pathological conditions involving the entire choroidal tract, as a sequel of the acute iritis. But for these diatheses, many acute cases which are followed by chronic iritis, would have returned to a state of health. It was not my desire to underestimate the importance of the iritic attachment, but to point out that as a factor in the production of recurrent iritis, it had been overestimated.

"If the views I have expressed are true, it renders less justifiable the operations for their detachment, *e. g.*, that devised by Streatfield, gently tearing them away by means of a blunt hook, which he inserted between the iris and lens capsule, or the Passavant operation, which consisted in grasping the iris at the point of attachment with forceps, and by traction detaching the adhesion. If the attachments are not so deleterious as was supposed, the risk following these operations is not to be justified.

"I have no doubt but that an eye constantly in a state of retino-choroidal irritation, in low grades of inflammation, as the result of strain in overcoming a hypermetropia or astigmatism, is more ready to take on all forms of disease, and may, therefore, as Dr. Little very fitly suggested, be more liable to iritis. Certainly, once attacked by iritis, such an eye would be more prone to disease of the choroidal tract and chronic or recurring iritis.

"It was not my wish to present eserine as a panacea, or even as a usual remedy to be employed in the treatment of sympathetic disease; but I reported the case in my paper as a clinical fact, the design being to set forth the value of this drug in improving the nutrition of chronically influenced eye-balls prone to set up sympathetic

irritation, especially where there is increased tension of the offending ball.

"I have had no experience in the use of electricity as an agent for hastening the absorption of vitreous facilities. Ophthalmologists, I am sure, would hail with pleasure any safe method which would accomplish a result so desirable. I should, however, use with great caution an agent, the powers of which are so imperfectly understood, in any eye with an inflamed retina and choroid.

"Dr. Fox has presented a very interesting history in his case of serous iritis, followed by sympathetic irritation. Such cases seem to shed light upon the vexed problem of the pathology of sympathetic irritation. One of the most interesting and important contributions to our knowledge of the subject, is that of Max. Kneis (*Vid. Archiv. Ophthal.*, vol. ix, page 125, N. Y.) In the case, the pathological histology of which he has so carefully presented, the disease had been apparently transmitted by the way of the optic nerves. The reported cases of sympathetic neuro-retinitis are getting more numerous, and it would seem that ere long we shall have to relinquish the term *sympathetic*—certainly for very many cases of disease communicated to the fellow eye—for some name which shall indicate its true pathology.

"Regarding the time after the iritic disease, when it is proper to perform iridectomy, I would remark that the symptoms in the individual case are probably the true guide for operative interference."

Editorial Department.

Periscope.

Note on Cholecystotomy.

Mr. Lawson Tait thus writes in the *Brit. Med. Jour.*, May 3, 1884:

The patient upon whom I first did this operation, the first successful one of its kind, and the second ever attempted, has remained in perfect health from the date of her operation, August, 1879, till now. I have performed the operation thirteen times, and all of the patients have recovered. One old woman died from suffocative catarrh some weeks after the wound was healed, and another case died of cancer of the liver, that being, in all probability, the cause of the distended gall-bladder, for I found no gall-stone which I could remove. Beyond the reach of my finger there was a nodule which, at the time, I believed to be an impacted calculus, but this was not confirmed by any *post mortem* examination, and the subsequent history was that of cancer.

The remaining eleven cases are in perfect health, and the results are perfect with one exception, and that exception has taught me a great deal.

It has, in the first place, satisfied me that my much-lamented friend, Dr. Marion Sims, laid down principles from which we are not likely to depart with any advantage, and that he practically perfected this operation, though he did not meet with a successful result in his own case.

Two modifications of the proceedings as advised by him have been suggested and have been put in practice; but they are not based on good reasoning, and have not been successful in practice. The first is a proposal made, I believe, by Sir Spencer Wells, to open the gall-bladder, remove the calculi, and to close it by a continuous suture without attaching it to the abdominal wound. So far as I know, this has been put in practice only once, and the result was fatal. A large quantity of bile was found in the peritoneum; and though this may not have been the cause of death, it is clearly a condition which is unlikely to contribute to success.

But the arguments against this proceeding are much stronger than the mere want of success in a single case. The gall-bladder is an organ subject to periodic filling and emptying, the latter process being accomplished by the contraction of its muscular walls, and this contraction is far more powerful than seems to be believed by any author I have consulted on this point. It also secretes an abundant quantity of clear albuminous fluid from its mucous surface, and this fluid contains—if I may make a conclusion from the few rough experiments I have made on the subject—some kind of ferment. Even if no bile enter the gall-bladder, it speedily fills with this secretion and expels it; so that, if its duct were occupied by a calculus, and a wound in its base were closed by a continuous suture, and not fastened to the abdominal wall, as recommended by Sir Spencer Wells, it is difficult to believe that such wound would remain closed.

It is a matter of extreme difficulty—in fact, I may say, it is impossible during the operation of cholecystotomy—to be quite certain that all the stones are removed from the duct. This canal is distended by the passage of a calculus, urged forwards by the pressure of the secretion of mucus by the gall-bladder itself. So long as the stone is in the cystic duct, the contents of the distended gall-bladder consist entirely of this clear mucus. After the stone has passed the mouth of the liver-duct, the bile flows into the gall-bladder, its passage into the duodenum is prevented, it is reabsorbed into the system, and jaundice is produced. The cystic duct, in its normal state, is of much smaller diameter than the common duct, and the agonizing pain of the passage of a gall-stone seems to be limited, in great measure, to this part of its journey, for it is rare, after these severe attacks, that jaundice occurs. After mild attacks jaundice occurs sometimes, and this indicates that the stone is passing, or has passed, through the common duct.

This leads me to say that, should cholecystotomy be performed whilst a stone is in the common duct, and the gall-bladder treated as recommended by Sir Spencer Wells, it is clear that the pressure

required to force the stone into the duodenum would be much greater than that required to tear open the stitched wound in the gall-bladder; extravasation of bile into the peritoneum ever afterwards would be inevitable.

Exactly the same argument is to be urged with still greater force against Langenbuch's proposal to remove the gall-bladder. The proposal is intrinsically absurd, for there can be no reason for removing any bladder merely because it has some stones in it. In many (five) of my cases the bladder was suppurating and greatly thickened, but the removal of the stones and the drainage of the bladder for a few weeks completely cured this condition. If the gall-bladder were removed at the time that a stone was lodged in the common duct, the bile must all flow, just as in the other case, into the peritoneum. I understand that Langenbuch's proceeding has been fatal in three out of six cases, where it is known to have been tried. It would have been fatal in three of my own cases if I had employed it, for in three of them stones were thus situated. In two I got the stones out, and in the third the stone is still there. Every drop of bile comes through the fistula, and not any appears to go through the intestines. The The fistula is a mere pin-hole, and I have tried to close it three times, always with the result of bringing on an agonizing colic which lasts till the bile forces its way out through the fistula. This takes about fifty hours. It is clear I shall not succeed in this way, and I propose to open the abdomen again, about an inch to the inner side of the gall-bladder, and crush the stone *in situ* by means of padded forceps applied outside the duct. If a better plan should occur to any of my readers I should be glad to have it, and if it should be practicable and successful, its originator shall have full credit for the suggestion.

Whilst watching these interesting cases of biliary fistula, I have read much of the literature of investigations concerning the function of the bile, and I have been greatly amused to see how utterly futile experiments on animals have been in settling even the most elementary facts of the influence and the uses of the human bile. Thus I have not seen the slightest evidence to believe that either quantity or quality of food, or any drugs which were used for the legitimate treatment of these cases, as morphia, calomel, podophyllin, and rhubarb, have the slightest effect on the quantity or character of the secretion. None of the patients have suffered in any way when even the whole secretion has come through the fistula, in one case for months, save from the inconvenience of the dribbling. Indeed, in a case still under observation, the patient has positively gained in weight, and has greatly improved in health. The stools are almost milk-white, and there is not the slightest evidence of the flatulence and decomposition which is said in the text-books to be the result of biliary fistula.

The conclusion of the surgical experience in these cases is, that the entire possibilities of the treatment of gall-stone and distended gall-bladder are exhausted in Dr. Marion Sims' original paper published in this journal, that no further extension of it seems possible, and that no further experimentation, such as that of Wells and Langenbuch, seems desirable.

Spontaneous Rupture of Hydrocephalus.

Dr. Allyn Reeve Manby thus writes in the *London Med. Times*, April 26, 1884:

On May 20, 1873, I was summoned to a primipara, who had been in labor twenty-four hours, and was suffering from too much inertia to deliver the head, which I accordingly did for her, with the forceps. The child was an unusually fine male, but had a large spina bifida of all the lumbar, and one or two of the lower dorsal vertebræ, the integuments of which were so thin and transparent, that the vertebral canal was distinctly visible with its contents, some of the fibres of the cauda equina ramifying just beneath the skin. There was also a peculiar deformity of the right foot, which was flat, like a negro's, with the heel projecting nearly as far back as the toes did forward. The child was dressed with the usual abdominal bandage, the pressure of which caused suppurative inflammation, and thickening of the surface of the tumor, so that by August of the same year nothing remained but a fleshy mass, pressure on which caused no discomfort to the child. About this time, however, the mother noticed that the head was "getting bigger," and that the child "stretched itself out and turned blue, as if convulsed, when she dressed it." When I saw it on October first, the child being then eighteen weeks old, it was decidedly hydrocephalous, but otherwise so well that no treatment was suggested or permitted. By Christmas, the head was so large and cumbrous that, when at home in London, the mother showed it to Mr. Jonathan Hutchinson, at the London Hospital, and I lost sight of the case till the evening of January 24, 1874, when the father came to tell me that the "head had burst, and that pints of water were squirting away," as indeed they were, for seven and three-quarter pints of slightly bloody serous fluid were collected in a pail, besides a great quantity which must have been lost on the floor, and in the mother's clothing, which were sodden, as she nursed it. The child seemed relieved by the discharge, and slept better than usual, taking and crying for the breast naturally; but it died in its mother's arms at 10:30 next morning, or seventeen hours after the oozing was detected.

The only measurement that had been taken during life was width from ear to ear, across the crown, and which was 27 inches.

Mr. Amyot published a very similar case (*Med. Times and Gaz.*, 1869), which lived twenty-four hours; and a case, aged ten and a half months (reported briefly in the *Med. Times and Gaz.*, April 14, 1869, p. 421), soon after this, by Dr. Frederick Brown, of Rochester, died ninety-six and a half hours after bursting, and the discharge of two quarts of coffee-colored fluid, on which the head "fell in, looking like broken pottery."

I was only allowed to make a very incomplete inspection, and by no persuasion or bribery could I induce the parent to part with the body for a museum. The aspect of the child was typical, according to Prescott Hewitt (*London Med. Gaz.*, 1844, or Watson's "Practice of Physic," fourth edition, vol. 1., p. 473), of intra-ventricular fluid, the facial skin being drawn upwards and outwards, arching the eyebrows, and rendering the supra orbital ridges prominent, the pupils of the eyes turned down, leaving the upper part of the

conjunctiva exposed. The skull presented the appearance of a large bowl, with jagged edges, the scalp having collapsed completelv, an appearance Trousseau somewhat poetically describes (Trousseau, "Clinical Medicine," New Syd. Soc., vol. i., p. 474), as "like the petals of an opening flower," but which Dr. Brown, with more truth, calls "a horrible and sickening sight." It measured, without allowing for the in-squeezing of the bones, as it was held, twenty-three inches round the edges, and half an inch more a little lower down, in circumference; probably, for the age of the child, it is one of, if not, the largest on record ; for a child of three years old, which Dr. Gardner, of New York (*Med. and Gaz.*, 1861, p. 259), exhibited in 1861, as having the largest head but one, "in or out of any museum," measured but twenty-three inches from the tip of one ear to the other, and thirty-seven and a half inches from the junction of the nasal bones to the os frontis, to the base of the occipital bone: he also gives the horizontal diameter as thirty-two inches, but as that would imply a circumference of more than eight feet, and as, moreover, he speaks of circumference further on, we must conclude that he means horizontal circumference. The scalp was thick and elastic, covered with large veins, and seemed to be structurally natural, with the exception of a rough reddened patch, the size of a shilling, about the middle of the left half, in the centre of which was a small pin-point hole, through which the water had passed ; on enlarging this, and raising the scalp, air rushed in with a whistling noise, and a little more water passed out. The brain was unrolled, and spread in a thin, coarsely reticulated layer over the inside. Ulceration and thinning of the membranes was evident beneath the red spot which had given way in the centre, as before described.

Cases of spontaneous evacuation of the hydrocephalic fluid may be found here and there in medical literature, but, excepting Dr. Brown's and Mr. Amyot's cases, none resemble mine. Mr. Greenhow, of Newcastle, published a case in 1852 (Newcastle Pathological Society, November, 1852), in which the fluid exuded through the scalp, without any definite opening, during the child's straining efforts, and cases of fatal and non-fatal rupture through the ethmoid bone and nares are mentioned by Trousseau (New Syd. Soc., vol. i, p. 477); Leonard Sedgwick (*Medical Times and Gazette*, March 15, 1856, p. 259), and others.

A curious case, the converse of mine, was shown at the Pathological Society in 1857, by Mr. Hutchinson (Pathological Society, *Medical Times and Gazette*, March 17, 1857), in which the head decreased, while a spina bifida in the sacral region oozed. The child ultimately died, and at the autopsy, the central canal of the spinal cord was found dilated to the size of a crow-quill.

On Acne in Fibre-Dressers.

Dr. Charles Atkin thus writes in the *Lancet*, May 31, 1884:

A dermatitis taking an acneform character, arising from an external irritant, is certainly uncommon. "Eczema," so called, in its various stages, is met with in many trades and occupations in all its varieties, from the "weeping vesicle" to the "leathery scaling skin;" but rashes of a tubercnlar form arising from external irritation of the hair-follicles have hitherto, as far as I know, been limited to those who work with tar, paraffin, benzoin, etc., or those cases where tar has been energetically used to cure some other form of skin disease, as psoriasis or chronic eczema. During last summer my attention was directed to a form of rash on the forearms and thighs of a certain class of workmen, different from anything else I had ever seen in those situations. The first case met with was in a healthy-looking, intelligent man, aged twenty-four, who described himself as a fibre-dresser, at which special department of brush-making he had been employed for the last two years. His work consisted in dipping a fibre called "kitool" and cocoa-nut fibre into some special preparation of various oils, soaking it, and then tearing and pulling it out. Since he has been employed at this work he has suffered continually from a rash, which itches and is sometimes painful. His forearms were more or less covered with raised tubercles, discrete, and presenting all the stages from the "black point" of the closed sebaceous gland to the suppurating, tense, and painful nodule. There were no pustules on the backs of the hands, but the "black points" were universal, and could be extruded by pressure or picked out by a needle-point. Wherever pustules had been were well-marked scars. The hairs on the back of the forearm were scanty, and could easily be pulled out with forceps, without any pain whatever. The same condition existed on the front of the thighs and shins, but more especially on the knees. There was no appearance of acne on the face, and only very scantily on the shoulders. Under the microscope the hairs treated with solution of potash were seen to be very swollen at their roots, with much adherent epithelium, evidently from proliferation of the lining of the hair-follicle. The man being otherwise healthy, with no appearance of struma, syphilis congenital or acquired, or scorbutus, the rash was evidently connected with his work. On being questioned, he informed me that he continually got his trousers soaked in front in dipping the kitool, and that he worked with his coat off and his sleeves rolled up. The next question was, What was the cause of the rash—the fibre or the oil? The former, which is a kind of coarse dried grass, produces no local ill effects on those who simply sort and pick it, causing only some throat irritation from the quantity of dust arising from it; therefore, the cause evidently lay in the liquid used. On procuring a sample of this, I detected a smell of paraffin in it, and learned on inquiry that it was not unusual to have this special oil mixture adulterated with this material. On visiting the place where the man worked, I found that all the men engaged in a similar occupation had acne more or less on their forearms, and that those who had been employed for some length of time were nearly absolutely hairless on those parts. Hebra says that when a rash is due to paraffin, etc., it does not usually come from direct contact of the irritant with the skin, but by the person living in an atmosphere impregnated with its vapors; such, however, can hardly be

the case here, for the rash is strictly localized to those parts which come in contact with, or are saturated by, the fluid, and also by the fact that it does not occur in those who only sort the fibre, though they are often at work in the same room. Again, it differs from acne caused by tar in that, Hebra says, the rash disappears on discontinuance of the irritation, leaving neither maculæ nor scars. Here the rash, though he was told it very much improved during a week's stay in the country, left most indelible marks of its former existence. Why should substances like mercury and antimony, acids, croton oil, cantharides, turpentine, and mustard, applied locally produce an eczematous dermatitis, whilst paraffin has apparently a very irritating effect on the hair-follicles and their adjacent sebaceous follicles, as they seem to be primarily affected; but why should not turpentine be equally so? The mildness and chronicity of the application may account for it; for it is well known that vegetable irritants cause a more acute form of dermatitis than the mineral ones; but that does not explain why the local application of mercury should not cause an acne as well as a papular eczema. In confirmation of the irritating properties of paraffin, Dr. Longmuir pointed out that epithelioma not uncommonly occurs in those who have to handle and work with it, but he does not mention whether he has noticed acne also. The fact of both acne and cancer having been attributed to the same irritant, suggests the question, Does traumatic acne ever go on to traumatic carcinoma?

Reviews and Book Notices.

BOOK NOTICES.

Second Annual Report of the State Board of Health of Indiana for the year 1883.

It is gratifying to see that the Indiana Board of Health is grappling with the problems of sanitation in earnest. Besides the general report, this volume contains various special articles, several of a notable character, as one on the health of the early settlers, br Dr. M. W. Latta; one on the hygiene of farmers' homes, by Dr. J. F. Hibberd; on restraint in the treatment of the insane, by Dr. W. F. Fletcher; on hog cholera, by Dr. J. M. Partridge, and others. The vital statistics of the State are set forth with fullness and accuracy by Dr. E. S. Elder.

The Alpine Winter Cure. By A. T. Tucker Wise. Baillière, Tindall & Cox, London.

The effect of cold, dry climates on chronic pulmonary disease is more and more recognized as beneficial. Probably nowhere can this be obtained with less sacrifice of the comforts of civilization than in Switzerland. This is true in winter as in summer, and the winter resorts in Switzerland are constantly increasing. In the volume before us, Dr. Wise speaks of Davos Platz, Wiesen, St. Moritz, and the Maloja. His information is full and from personal knowledge, and it will prove satisfactory to invalids and health-seekers. He also gives many general suggestions to travelers in Alpine climates, and they are well worth perusal by all.

Student's Manual of Electro-Therapeutics. By Dr. R. W. Amidon. G. P. Putnam & Sons, 1884.

The need of a brief manual of the essentials of electrical treatment has induced the author to present them in the least technical manner in the volume before us. Our only criticism upon it is that it is so very brief that it offers but an inadequate idea of this branch of therapeutics. The illustrations are reasonably numerous and well printed.

Hooper's Physicians' Vade Mecum, Vol. II, Wm. Wood & Co., New York city.

We have previously referred to this work on the appearance of the first volume. The present issue briefly sets forth the various special diseases, and completes the work. It is a member of Wood's Library of Standard Medical Authors, and will be appreciated by the subscribers to that valuable series.

An Introduction to Pathology and Morbid Anatomy, by T. Henry Green, M. D. Fifth American edition. Henry C. Lea's Son & Co.

This convenient brief treatise now appears with a careful revisal of the author, and is presented on excellent paper and with admirably printed cuts by the publisher. A number of new points have been added to previous editions, and the rapid increase in this branch of medical science has been closely followed up. We can recommend this work as of as great practical utility as any with which we are acquainted on morbid changes.

Scarlet Fever in Huntingdon.

Advices from Huntingdon (this State) say that scarlet fever and scarlet rash have prevailed so long in that city that they have ceased to excite special comment, and people have become as familiar with their presence as with anything else with which they have daily contact. It is almost a year since these diseases became epidemic, and in that time they have visited fully one-third of the families in the city. In April last the public schools were closed for several weeks, and when they were reopened it was thought the danger was past; but it soon became as great as ever, and there has since been no abatement, nor does there seem to be any probability of a change until the diseases have gone through the families that have thus far escaped. There have been some deaths, but not a great many in proportion to the total number of cases. The schools closed about two months ago for the summer vacation, but the spread of the diseases has since been as great as it was before.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

HYDROPHOBIA.

In the *Medical Times and Gazette*, London, England, December 1, 1877, Edw. Wolfenden Collins, M. D., F. R. C. S. Ire., Surg. to Jervis St. Hospital, writes:

"For the treatment of hydrophobia it would appear that in curara we have a valuable therapeutic agent; and I desire to strengthen the hands of the editors of the *Lancet* and *Medical Times and Gazette* in their recent able editorial comments on this subject. In these articles it has, I think, been too hastily assumed that no proof exists that any case of genuine hydrophobia has ever been cured, unless it be that recorded by Dr. Offenburg, of Wickrath, in 1874, to which allusion is made (*Medical Times and Gazette*, October 6, 1877). It is my object to show that this statement, which has so far escaped criticism, does not represent the sum of our therapeutic knowledge regarding the successful treatment of this disease. The other two recent cases, which I shall bring under notice, are besides of much value, as they point exactly in the same direction as that of Dr. Offenburg, and taken together with it, warrant the hope that in similar cases, curara, when pushed rapidly to the manifestation of its peculiar physiological effects, may be found equally efficacious.

"In the *Amer. Journal of Medical Sciences*, July, 1876, page 81, Dr. B. A. Watson, of Jersey City, minutely discusses and gives the fullest particulars of a case which he and Prof. Austin Flint regarded as an instance of true rabies canina. The symptoms of rabies developed themselves forty-seven days after the individual—a strong, healthy man, forty-five years of age—had been bitten in the finger by his own rabid dog. His servant-girl, who had been bitten at the same time and by the same animal, died five days before the commencement of her master's illness, of unmistakable hydrophobia. In this man's case there was a gradual increase in the severity of the symptoms till after the subcutaneous administration of curara in full and rapidly-augmenting doses ($\frac{1}{16}$ gr., $\frac{1}{9}$ gr., $\frac{1}{6}$ gr.) every third hour. The unfavorable symptoms forthwith subsided, and disappeared completely after the third injection.

"The second case was treated by Dr. Polli, and an abstract of it appeared in *Le Paris Med.*, May 17, 1877. A child, twelve years old, had been bitten by a rabid dog eighty days before the manifestations of the hydrophobic symptoms. Subcutaneous injections of morphia and chloroform inhalation having been tried without success, curara

was injected subcutaneously on seven different occasions within the short space of five hours and a half. During this period twenty centigrammes (three grains) of curara were injected. The hydrophobic symptoms quickly subsided, being replaced by paralytic phenomena of a very pronounced character. Two days subsequently some renewed hydrophobic symptoms were completely banished by a fresh injection of three centigrammes (nearly half a grain) of curara. The child slowly recovered.

"In Dr. Offenberg's case (*Medical Times and Gazette*, October 6), where characteristic symptoms of rabies manifested themselves in a woman aged twenty-four, eighty days after she had been bitten by a rabid dog, the subcutaneous injection of one-third of a grain of curara at intervals of fifteen minutes at first, and subsequently at intervals of an hour, resulted in the cessation of the hydrophobic symptoms, and the supervention of general paralysis, rendering artificial respiration necessary. In this case, within the space of four hours and a half, seven injections were used, representing altogether nineteen centigrammes (nearly three grains) of curara. On the evening of the third day renewed hydrophobic symptoms, which had assumed a serious aspect, were promptly controlled by one other injection of curara.

"If it be conceded that these well-authenticated cases were instances of genuine hydrophobia (as their narrators with good reason maintain, from a careful consideration of their history and all the symptoms), they are uniformly and highly suggestive as regards a method of treatment of this malady which hitherto has not received the attention it thus demands. More than ten years ago, Trousseau, when suggesting the possible advantage of the subcutaneous administration of curara in hydrophobia, was not deterred by the want of success which had attended its use in tetanus. 'Perhaps the want of success,' he remarks, 'may be largely due to the mode of administration of the drug' (*Clinique Medicale*, vol. ii, p. 380). This, it appears to me, is the point on which these three cases are so instructive. They demonstrate that, to be of service, curara must be employed in full and (probably best of all) in rapidly augmenting subcutaneous doses, varying from one-tenth to half a grain, at short intervals, until the paralytic symptoms, which experimental physiology has taught us to recognize as the manifestation of the full influence of the drug, begin to develop themselves. At this stage artificial respiration may even become necessary, as in Dr. Offenberg's case. The variation in strength of specimens of curara renders it important that the injection fluid should be procured from those who are likely to have exercised special care in the selection of the drug. A solution so concentrated (half a grain in five minims) as that prepared by Messrs. Gale, of Bouverie street (*Lancet*, Nov. 10), if reliable, seems to supply such a desideratum."

Notes and Comments.

Borate of Quinine.

The amorphous borate of quinine is an amber-yellow, almost crystalline-looking powder. It has a mild, bitter, by no means disagreeable taste, and is soluble in equal parts of water. As the drug can be sold much cheaper than sulphate or muriate of quinine, and as its taste would specially adapt it to the diseases of children, Drs. D. Finkler and D. Prior in Bonn, instituted a series of observations for the purpose of determining its effect. (*Deutsch. Med. Wochensch.*, 6, 1884.) The results were as follows:

The remedy was administered in doses varying from 8 to 16 grains. These doses were given every half or every hour, so that within from two to four hours *in maximo* 48 grains were used.

For the purpose of discovering how the drug is borne by the stomach, it was tried in many cases of tuberculosis, and in those of acute and chronic gastric catarrh. Some of those patients were in the habit of vomiting when they committed the least error of diet. *In none of the very numerous cases did the borate of quinine ever cause vomiting.* Even in phthisical patients suffering from chronic catarrh of the stomach, and being very sensitive to any nauseous drug, the remedy never induced any augmentation of their gastric troubles.

The drug had not only the same anti-febrile effect as quiniæ sulphas, but it had also besides a peculiar disinfecting action upon the intestinal canal, and in patients, who had used the remedy for a number of weeks, not the least deleterious influence on stomach or intestines was noticed. In patients suffering from high fever, and having previously vomited after calomel and muriate of quinine, the borate not only caused the same reduction of temperature, but it was also well borne by the stomach. It seems to be specially well borne, if a larger quantity of water or a small dosis of brandy is taken after it. It never produced tinnitus aurium. One of the experimenters, suffering from a severe nasal catarrh, took two doses of eight grains each without any bad

after-effect, while the same doses of muriate of quinine usually caused a sleepless night, in consequence of the violent buzzing in the ears.

The administration of borate of quinine in the evening induced a reduction of temperature in the morning; if it was taken in the morning, a fall of temperature was notice at about 2 p. m., while if then a dosis was given the temperature declined in the evening, so that in this respect the borate also resembles the effect of the muriate or sulphate of quinine.

Considering, therefore, the cheapness of the remedy, and the fact that it has the same effect as the quinine salts usually employed, and considering its greatly better taste, and the fact of its being well borne even in large doses by the most delicate stomach, its general introduction probably will be but a question of time. Its antipyretic, as well as its disinfecting action is probably due to the boracic acid. It is manufactured in Germany and there sold for but half the price as sulphate of quinine.

The Castration of Women.

The *Med. Times and Gaz.*, April 12, 1884, says:

A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an article by Dr. Wilhelm Tauffer, of Buda-Pesth, on the above subject. He relates twelve cases of this operation performed by himself, and then presents the conclusions which follow. We cannot say that this author is as cautious in drawing inferences as we should like, but we give his propositions, which must be taken for what they are worth:

1. Castration is an operation which with proper care is not attended with any great risk: the unavoidable mortality being now less than ten per cent.

2. The operation should be performed with antiseptic precautions and under carbolic spray; the abdominal cavity should be closed; drainage is only exceptionally required.

3. The limitation, that castration is not called for when the climacteric is near, can only be conditionally accepted, because the age at which the climacteric occurs is very different in different individuals, and cannot be foretold.

4. The condition laid down by Hegar, that the ovaries should be distinctly felt before their extirpation is attempted, is an impracticable one.

5. Both ovaries should be removed, even if the disease be limited to one; excepting in cases where special circumstances make it desirable to leave behind the apparently healthy ovary. The reason for removing both ovaries is, that the remaining gland has a tendency to become diseased in the same way as its fellow.

6. It is generally desirable to remove the tubes as well as the ovaries; and it is unconditionally necessary if there be the slightest appearance of disease in them.

7. Hystero-epilepsy is curable by castration.

8. The symptoms grouped together under the name of hysteria, when rightly analyzed, can often be traced back to ovarian disease.

9. The question as to the influence upon uterine fibroids of the ligature of large nutrient vessels going to them, without castration, is worth consideration.

10. With regard to prognosis it is important to remember that the menopause only follows immediately upon the operation in those cases in which the neighboring organs are not diseased; but all inflammatory conditions of them delay the climacteric.

11. The final result of castration can only be determined after the lapse of months.

12. It must be regarded as an open question how far diseases of the female sexual organs influence the development of certain psychoses.

13. So must the question whether such psychoses are curable by castration.

14. In the interest of unity and comparison of observations, it is desirable that the classification of cases (suitable for this operation) adopted by Hegar should be generally accepted.

Hysterical or Nervous Breathing.

The characteristic features of most of these cases are cough, with or without blood-spitting, usually of a venous character, with very rapid and very shallow breathing, and absence, as a rule, of physical signs of disease. Such is the general description which Dr. W. Martin Coates gives in the *Brit. Med. Jour.*, July 5, 1884, of a manifestation of hysteria, which, while not common, has yet presented itself to him several times during the past twenty years. The following case is selected from those which he records:

Case 1. This lady, aged 30, is one of a very sensitive family. Her history was a sad one. She had been married to one to whom she was devotedly attached. Three weeks after marriage, he died of hæmoptysis. A year after this, she called to consult me, with the preface that she knew it was of no use, as one of her lungs was diseased. She told me that she had a constant cough, and that she frequently spat blood. She had consulted an eminent practitioner at a wintering sea-side place. She said that he had told her

that the upper part of the left lung was diseased, and that he felt great anxiety about her. I examined her chest, and found nothing abnormal, except very quick and almost imperceptible vesicular breathing on the left side. I could not induce her, for a long time, to draw a long breath. This is a marked peculiarity of these cases. At last, I told her to count twenty without drawing breath. She did so, and then she expanded her lung perfectly, the air entering freely into every part. I expressed to her a conviction that her lungs were healthy. She was much offended, and gave me to understand that I was mistaken. This taking of offence at being told that at which a healthy mind would rejoice, gave me the first hint that I had to deal with a mind morbidly craving for sympathy. Some months after this, she called again, and told me that she had consulted Dr. C. J. B. Williams, who confirmed my diagnosis. She is still alive, but ever an invalid, with simulated disease. Sometimes it is neuralgia, sometimes constant vomiting, at others asserted amenorrhœa. At present, she has what she has been told is "angina pectoris;" but, as it attacks her only at night, and not when ascending a hill or when walking against the wind, it is, of course, nothing of the sort. She has long since lost her cough and blood-spitting.

The treatment must, of course, be the same as that pursued for any other hysterical manifestation.

The Efficacy of Iodoform in Preventing Uterine Colic and Pelvic Inflammation Following the Intra-uterine Application of Nitrate of Silver.

At the recent meeting of the Medical and Chirurgical Faculty of Maryland, Dr. Sellman read a paper with this title, which was a practical one, and gave in detail Dr. Sellman's experience with these agents. He began by saying that, in the majority of cases of endometritis, applications of nitrate of silver (gr. lxxx ad f. ℥ j) had been the most useful agent he had used. Perfect cure or great relief followed its repeated use, and he had never seen stricture or closure of the uterine canal follow. But a serious objection to it is that not unfrequently his patients would suffer severe attacks of uterine colic either immediately after the application or within an hour, and he had seen pelvic peritonitis and ovaritis brought on by it. He then recounted a case of this kind. To relieve the colic, which was of common occurrence, he tried belladonna, opium, and hyoscyamus, without effect. Knowing the anæsthetic power of iodoform, he tried that, and has never since had any after-trouble from the application of nitrate of silver. As to the cause of the uterine colic, he said that in congestive and inflammatory conditions of the uterus there exists, as a rule, a state of hyperæsthesia, and a nervous condition of the whole organism. The application causes the cervical canal to contract, and prevents the excess of fluid from discharging into the vagina. He never had a case of uterine colic with dilated canal. Pelvic inflammation following the applications he thought due to the excess of fluid being forced into a patent Fallopian tube. He never had a fatal case, but they caused much solicitude. His method is to make the application of the nitrate of silver solution on a cotton-wrapped applicator, immediately following it with powdered iodoform applied in the same manner. Sometimes the cervical canal contracts so suddenly and violently as to prevent the applicator being passed the second time. Under such circumstances he inserts a suppository or uterine bougie medicated or charged with iodoform. He covers the cervix thoroughly with iodoform, and sometimes saturates a pledget of cotton with iodoform and vaseline, leaving a string attached for the patient to remove it the next morning. These procedures have prevented all unpleasant after-effects.

Anthrax.

An ox having died from malignant pustule, was cut open. The intestines were removed by a butcher, æt. 64. Twenty days later a pustule developed itself on the forearm of the butcher, and caused an extensive inflammation and infiltration of the surrounding skin. The parts affected were then removed by an operation. The microscopical examination of a piece of the diseased skin showed besides the well-known morbid histological elements the bacilli of anthrax in great numbers, in the exudation between the papillary bodies and the rete Malpighii. Some were found also in the papillæ. The greatest quantity of bacilli was discovered in the middle of the pustule. None of the bacilli had penetrated into the blood-vessels, sebaceous glands or roots of the hairs, which fact may explain the eventual recovery of the butcher.

The patient was in charge of Dr. Bleuler (*Corr. Bl. f. Schweiz. Aerz.*, 7 and 8), who proposes to practice a similar protective inoculation in persons, whose occupation frequently brings them in contact with cattle or sheep suffering from anthrax, as has been employed by Pasteur and others in animals. As well known, a drop of the blood

containing the bacilli of malignant pustule is added to a small quantity of chicken—bouillon—which while being kept sterile, is exposed for about two weeks to the atmosphere. Then a drop of this fluid is added again to a similar quantity of chicken-tea, and this exposed to the air. In this manner at last a fluid is obtained which, when injected into the circulation, for instance, of a sheep, will effectually protect the animal against the infection by anthrax, while scarcely causing a local irritation. Thus far the experiment has not yet been tried on the human being. It may, perhaps, be finally proven that we can make thus "disease-proof" every individual exposed to the influence of infectious maladies. Who will make the first trial with the poison of cholera?

Idiopathic Ascites.

The Jour. de Med. et de Chirurg., May, 1884, says that Dr. Toulze defines this affection as an ascites occurring suddenly in a previously healthy individual, continuing for a variable time with perhaps one or more relapses, but terminating finally in recovery. Its cause is found in a sudden chill, either from external influences or from the ingestion of very cold fluids, or it may come on after the sudden suppression of the catamenial flow or the recession of an exanthematous eruption. It may exist as an acute, a subacute, or a chronic condition. The acute form is accompanied, as a rule, by a rather intense pyrexia. The abdomen is more or less distended with fluid, which gives rise to the usual functional troubles. The subacute form is of longer duration and presents the same symptoms, though in a less pronounced degree. The chronic variety is characterized especially by the frequent relapses. The course and duration of essential ascites are naturally very variable; but that which characterizes all the different forms is the favorable termination. A spontaneous cure almost always obtains by crisis at the end of a month or two, sometimes more, sometimes less. The fluid is carried off by way of the kidneys, the skin, the intestines, or even, in some cases, by the mammary glands. Instances have been noted in which an increased secretion took place from accidental wounds or from ulcerated surfaces, the ascitic fluid finding vent in this way. The treatment consists in favoring by derivatives the removal of the fluid. Diuretics and drastic purgatives are especially indicated. Paracentesis should be reserved for those rebellious cases which seem to resist the action of internal remedies.

Meconium in Its Forensic Aspects.

Dr. J. Ch. Huber (*Friedreich's Blätter für Gerichtl. Med.*, 1884, pp. 24, 142) treats this subject elaborately, and gives a bibliography extending from the time of Aristotle downwards. According to his own observations, the most important substance found in meconium is that greenish-yellow body which more especially determines the color of the dark greenish-black masses. These bodies, which Tardieu admirably depicts in his *Study of Infanticide*, are mostly of oblong, elliptical, oval, or roundish contour, and are not unfrequently flaky with rounded angles. In size, they range from that of a microcyte (and less) to that of a squamous epithelial cell from the tongue. As these bodies, which appear to be altogether homogeneous in structure, are enveloped in mucus, it is very difficult to ascertain how they behave towards chemical reagents, which penetrate them slowly. They are unaltered by acetic acid and by ether, but dissolve in solution of potash. The bile-pigment reaction has been obtained from them by good observers. It is more difficult to decide what is their basis (albumin or keratin?), whence they arise. When we take into consideration the abundant shedding of epithelium in the small intestine of the fœtus, Huber cannot avoid the conclusion that we have here to do with intestinal epithelial cells, which have become swollen, confluent, and disintegrated. On account of their frequently characteristic form, and the ready possibility of their detection in dried meconium stains, he holds these bodies to be of great importance, and, at any rate, as much more characteristic than those amniotic elements which have been swallowed.

Myositis Ossificans Progressiva.

A man æt. 23, had been ailing from his earliest childhood. When nine years old, he had made the first attempt at walking. His family evinced no neuropathic history. Exposure to cold and rheumatic affections could not be elicited as pathogenic causes. Besides atrophy of the muscles and at some places their total disappearance, some were truly ossified, and peculiar ankyloses had formed. The latter were especially noticeable in the spinal columns and in the joints of the jaws. Notwithstanding the long suffering of the patient, his general health was not greatly disturbed, and he complained only when, as would happen every few months, a local swelling developed itself in some of the affected muscles. Dr. O. Kohts, who reports this rare case in the *Jahrb. f. Kinderheilk.*

xxi. 3, says that he saw but once ossification happen at the place of the local swellings. The urine evinced nothing abnormal. Faradic muscular contractility was preserved in the affected muscles. It was not so strong, as in healthy muscular fibres, but considering the diminished quantity of muscular tissue, electric excitability was not leslened, or in other words, those muscular fibres, which were still preserved, showed a normal electric reaction. Intelligence, taking into consideration the general condition of the patient, was not affected. The malady is probably purely a disease of the muscles.

Ephemeral High Fevers in Children.

How often are we called to a sick child with a high temperature and a bounding pulse, the family anxious, and we, ourselves, half inclined to expect a most serious disease, when, lo and behold, in a few hours the child is laughing and playing as though sickness had never been even thought of. It has proved to be merely an ephemeral fever. Dr. Henry N. Read publishes a paper on this subject in the *N. Y. Med. Jour.*, July 19, 1884, in which he gives the following points which may be taken into consideration in endeavoring to make a diagnosis between these ephemeral fevers and others of a specific or symptomatic nature:

1. The absence of any local inflammation, or of the history of any recent injury.

2. The abrupt beginning, without prodromes; the rapid rise in temperature; the early severity of the febrile symptoms, commonly greater at the commencement than in either enteric or typhus fever.

3. The duration is very short, usually not more than twenty-four hours—oftener less than more.

4. Absence of eruption.

5. Absence of the abdominal symptoms of enteric fever and the circulatory symptoms of meningitis.

6. Absence of jaundice, or of the enlargement of the spleen and liver which marks malarial and relapsing fevers.

7. Absence of epidemics of all kinds.

Treatment of Stomachic Dyspepsia.

In the *St. Louis Med. and Surg. Jour.*, April, 1884, Dr. John H. Duncan says:

I regard the quietude of mind and body, however, of as much, if not more, importance than the drugs. Among the best stomachic tonics are pepsin, the simple bitters, for they contain neither astringent nor aromatic properties, they increase the flow of the juice simply by their bitterness. One of the best preparations of hydrastis is the fluid hydrastis, for it contains neither alcohol nor a resin, and is therefore non-irritating. In such conditions, I always advise the use of some sour wine, either just before or during the meal. It is of the greatest importance that the patient does not overload the stomach and consequently it would be far better that he, if it is convenient, does not confine himself to the regular three meals a day, but eat oftener and a smaller quantity, thus giving the stomach the time and opportunity to digest its contents. If the dyspepsia is due to an over-abundance of gastric juice which can be ascertained by the acid eructations after digestion is completed, I would give the dilute phosphoric acid directly after meals. I give it upon the principle that acid applied directly to the mouth of a secreting gland diminishes its secretion. The pyrosis, cardialgia, and acid eructations of any form of dyspepsia, are relieved by alkalies. If the dyspepsia is due to the depraved condition of the blood, thus affecting the quality of the gastric juice, I would give blood tonics; and in fact, in any form tonics are advisable. The only treatment for dyspepsia due to alcoholism is the withdrawal of the alcohol and the use of such remedies as are used when there is simply indigestion due to a deficient quantity of blood to the peptic glands.

Cause of Epilepsy in the Brain.

In *Du Bois-Reymond's Archiv.*, 1884, p. 79, the following interesting experiment by Dr. S. Danillo, is reported:

While under the influence of ether a dog, which had first received a subcutaneous injection of morphia, was operated upon. The cortical surface of a whole half of the cerebrum was carefully dissected off. About half an hour later the parts were electrically irritated in the manner, first recommended by Du Bois-Reymond. When the anterior parts were excited (the motor-sphere) spasmodic contractions were plainly observed, while the whole posterior layer was almost insensitive to all electrical impressions. But if the current was very strong and applied for a longer time, the same phenomena happened, and the irritation seemed to spread to the deeper lying parts.

Dr. D. draws the conclusion from these experiments, that the cortical gray matter of the posterior part of the brain is the original starting point of an epileptical seizure. Besides our knowledge of the local function, not much benefit will be de-

rived from these investigations, as they make surgical interference but still more problematical than it is at present, and medical treatment appear as useless.

Sclerotinic Acid in Epilepsy.

From *Le Progrès Mèd.* we learn that in December, 1882, four epileptic children were treated with the following solution:

℞. Sclerotinic acid. grs. vijss to xss.
Distilled water, f. ℥ ijss.
Carbolic acid, grs. xss.
M. S. Each injection should contain from gr. $\frac{1}{25}$ to $\frac{1}{12}$.

For hypodermic use, the dose has not been greater than gr. $\frac{1}{12}$. The duration of the treatment was six weeks for one child, which died; six and a half months for two others, and seven months for the fourth.

For internal administration, the acid is given in an aromatic adjuvant (*julep*), morning and evening. Eight epileptics have been treated in this manner, the dose of sclerotinic acid progressively increasing by about gr. $\frac{1}{6}$ every week. The average duration of treatment for these eight patients was three hundred and fourteen days. Of the twelve patients treated by both methods, only five have been improved. These results are not very encouraging, but, under the circumstances, it may be worth while to experiment still further with this drug.

Pilocarpia in Exudations.

For several years Dr. De Dominicis in Italy has employed pilocarpia in pleuritic and peritoneal exudations, and his success has been so uniform as to induce him to consider the non-absorption in any such a case to be due to some existing complication. He uses pilocarpia only subcutaneously. In his opinion it causes an increase in the heart's action, save during the period of active diaphoresis when the pulse becomes slower. He has also discovered that the addition of quinine or caffein diminishes the therapeutical effect of the drug. About a year ago some German observer reported, that if jaborandi is given in a cup of strong coffee, its weakening influence on the heart is not noted, and in D.'s observations we now find an explanation of the doubtless correct statement.

Some Formulæ for Irritative Diarrhœa.

At this time of the year when irritative diarrhœa is so very common and so apt to prove serious among children, we are pleased to note some formulæ that have been found very useful by Dr. E. H. Bartley (*New York Med. Jour.*, July 19, 1884):

℞. Ol. ricini, f. ℥ iv.
Bismuth. subnitratis, ℥ ij.
Magnes. carbonatis, ℥ j.
Sacchari, ℥ ij.
Ol. anisi vel ol. menth. pip., ♏ vj.
M. Sig.—℥ j. for a child of six months to one year.

Or we may use:

℞. Vin. pepsini, f. ℥ jss.
Bismuth. subnit., ℥ ij.
Glycerini, ℥ iv.
M. Sig.—℥ j. at a dose.

Dr. Mecray, of Cape May, New Jersey, highly recommends the following:

℞. Ol. ricini, ℥ iv.
Tr. opii, gtt. iv.
Pulv. acacea,
Sac. alb., q. s.
Aq. menth. pid., ad. ℥ ij.
M. Sig.—Dessertspoonful every three hours.

Treatment of Cholera.

From the *Med. Record* we read that Horner's anti-cholera mixture, recommended by Hartshorn and Bartholow, may be used before or at the beginning of the stage of collapse:

℞. Chloroform.
Tinct. opii.
Spts. camph.
Spts. ammon. aromat., āā f. ℥ jss.
Creasote, gtt. iij.
Olei cinnamomi, gtt. vij.
Spts. vini gall, f. ℥ ij.
M. Sig.—Gtt. x. to xx. in ice-water every five minutes.

A hypodermic injection of morphine is a most effective remedy for the diarrhœa and cramps.

Cholera specifics do not exist. Oxygen, saline venous injections, chloride of sodium drinks, warm baths, calomel, camphor, venesection, have all failed.

Deafness in Syphilitic Tabes.

From *L'Union Med.*, June 14, 1884, we learn that Dr. P. Hermet, in an article on this subject, draws the following conclusions:

1. Deafness in syphilitic tabes is due to a deep lesion.

2. Its evolution is very rapid, and it may be considered as a symptom of the preataxic period.

3. It is an element in making a diagnosis, and when one observes sudden deafness in a syphilitic, without apparent lesion, other symptoms of locomotor ataxia should be carefully looked for.

Scarlet Fever in Pregnancy.

Dr. Charles A. Leale thus concludes a paper in the *Med. News*, May 31, 1884:

Scarlet fever may attack the fœtus in utero.

The large proportion of children born with scarlet fever recover.

Scarlet fever of the newly-born child has like manifestations as when it occurs later in life.

Scarlet fever may attack the woman during pregnancy, and also immediately after childbirth.

Scarlet fever is exceeding fatal to the woman during pregnancy and during parturition.

Scarlet fever rarely, if ever, affects the parturient woman if she has had a previous attack.

Scarlet fever causes death in the parturient woman by coma, exhaustion, or by convulsions.

Scarlet fever being a self-limited disease, is best treated by relieving dangerous symptoms, and in accordance with the rules of hygiene.

Scarlet fever only exceptionally occurs during the ages that women bear children; therefore, the proportion of those liable to contract the disease during pregnancy and childbirth, must necessarily be small.

Scarlet fever and septicæmia are distinct diseases, being unlike in many respects.

Sialorrhœa of Nervous Origin.

The Paris correspondent of the *Brit. Med. Jour.*, May 10, 1884, says that M. Gilles de la Tourrette furnishes an interesting observation of a case of sialorrhœa of nervous origin. The patient presented neuropathic antecedents. He was suddenly attacked by violent neuralgic pain in the cheek and maxillary region, which was quickly followed by an abundant flow of saliva, presenting all the characteristics of the parotid secretion; it was thready and viscous. The quantity excreted amounted to 1,200 grammes, exceeding the quantity excreted after administering a sialogogue. The seat of the pain was swollen, and presented a marked hyperæmic coloration, which increased or diminished according to the degree of pain. The saliva which escaped was almost exclusively of the parotid, which is never obtained in an isolated form by means of sialogogues.

Hæmaturia Caused by Retention of Urine.

Guyon, in the *Jour. de Med. et de Chir. Prac.*, states that long-continued retention of urine is always accompanied by a considerable venous congestion of the bladder, prostate, kidneys, and tissues around the bladder. When the bladder is emptied rapidly and completely with a large catheter, the sudden dimunition of pressure may cause ecchymoses in the mucous membrane, and sometimes abundant hæmorrhage, syncope, and death. In these cases, one-half only of the urine should be drawn off very slowly. It is a good plan also to inject into the bladder 150 grammes of a 4 per cent. solution of boracic acid, so as to prevent decomposition.

Permanent Pills of Permanganate of Potassium.

According to a correspondent of the *Deutsche Medizinal-Zeitung*, a Russian Pharmacist has hit upon an expedient for preventing the change which the permanganate is prone to undergo when made into pills. The formula is as follows:

℞.	Vaseline,	2 parts.
	Paraffin,	
	White wax, each,	1 part.
	White bole,	3 parts.

The vaseline, the paraffin, and the wax are to be melted together, and when the mixture is cold, the bole is to be added. The permanganate of potassium is to be reduced to a fine powder in another mortar, and then added to the mass. The pill-machine used should be of horn or of wood.

Correspondence.

Larvæ of Œstrus Bovis in Human Skin.

Eds. Med. and Surgical Reporter:

From the great rarity of the ova of the œstrus bovis (gad-fly) being deposited into the human skin, and larvæ being developed, I consider the following case of interest to report:

The patient, an infant two weeks old, prematurely born at seven and a half months, being in a delicate condition, bottle fed, but thriving fairly well up to the time the nurse first noticed a swelling about half the size of an acorn on the anterior part of the neck; the same day, later, numerous similar swellings appeared in the same locality, posterior part of neck, chest, and between the fingers of both hands; the morning of the second day the centre of each swelling changed to a dark red; a few burst that evening, giving vent to a dark, bloody discharge, when the white grub could be seen making his way out; by the third day most of the swellings had opened, and out of each the nurse pressed out a worm, saying about forty in all were extracted.

I first saw the infant on the third day, when it presented a hideous sight: emaciated, jaundiced, and its neck, chest and hands perforated, each opening exuding a very foul-smelling discharge. I was able to press out of several openings the larvæ, and found them to be those of the gad-fly, measuring from $\frac{3}{16}$ to $\frac{5}{8}$ of an inch in length, and about $\frac{1}{8}$ of an inch in thickness.

The infant from the time of the first swelling

had considerable difficulty in swallowing, which increased; whether or not it was due to the same cause I am unable to say, as port-mortem was not allowed. It died the third day of the complaint.

The fly must have deposited its eggs directly through the skin, as there was no wound or abrasion of it, and from the fact that the larvæ were developed at distant points, it does not seem that the ova were introduced at all of the different points, but that either they moved, or the grub in the incipiency of its development found its way to distant localities. A similar peculiarly is claimed to be possessed by the filiaria medinensis (guinea worm).

F. Shimoner, M. D.

St. Paul, Minnesota.

News and Miscellany.

The Elk County (Pa.) Medical Society.

(Reported by Spencer M. Free, M. D., Secretary.)

The first meeting under our new officers was held at St. Mary's on Thursday, July 10. We were glad to welcome to our number three new members—gentlemen who have recently located in the county. There being no society in Cameron county, the jurisdiction of our Society was extended over that county.

Nearly all of our number not already members of the American Medical Association accepted the provision of the amendment to Regulation II., adopted at Washington in May last.

I mention this simply to let other societies of the State know how we stand on that question.

A matter of more importance to us individually and as a State, is the subject of a State Board of Health. Our Society unanimously adopted a resolution approving the "Pennsylvania Association for securing a State Board of Health." This subject has been discussed for some time by us, and we finally organized ourselves into a voluntary board of health for our two counties, to act, so far as we could, at the disadvantage of having no authority or means to enforce discipline.

We have a series of printed blanks similar to those of cities for the reporting of births, deaths, and contagious diseases. These reports are handed to the Secretary of the Society at each regular meeting. By this means we hope to collect valuable statistics, and to hasten the establishment of a State Board of Health. It occurs to me that if all of the societies of our State took similar action, it would do much good to themselves, their patrons, and for State sanitary legislation.

The announcement being made that Dr. B. F. Baer, of the University of Pennsylvania, expected to visit the county, a committee was appointed to extend him greeting and welcome, and to request an opportunity to show our hospitality.

An excellent essay, which elicited much discussion, was read by Dr. Hoffman. Subject: Exophthalmic Goitre.

The following cases were reported; some of them were present and were examined:

By Dr. Hartman—A case of obstinate granular ophthalmia. The treatment advised by the Society had also been advised by the doctor, namely "send him to a good specialist."

By Dr. Straight—A case of "wrist-drop," which was interesting because of its history and difficulty of finding the cause.

Dr. Free presented a man with double Colles' fracture. It is interesting only because of treatment. The left arm was put up in a splint, and the right one in adhesive plaster and muslin bandage, according to Moore. The result was better in the left arm. There is less deformity and more motion.

Two cases of disunited fracture of lower bones of the leg were presented. Dr. Hartman's case was of four months' standing. It had fallen into his hands only recently; having had very poor treatment before. A permanent dressing was advised and thought to be sufficient.

Dr. De Long's case had existed twenty weeks when he was called. The case then bore a history of necrosis, and removal of a few small pieces of bone. He put in a Pancoast screw. The man got well and walked on the leg for three months. He now has disunion at point of fracture, with further indications of necrosis.

Dr. Wilson reported a case of tetanus. Cause: Traumatism. It has been of five weeks' duration. At present, the patient is improved, and recovery is expected. During the early course of the disease, spasms were frequent and violent. Quinia and morphia were given freely—the morphia in large doses (from one-half to one grain each hour until spasms ceased). A pill containing strychnia and physostigma was used later in the disease, but with no apparent benefit. Now he is giving one-sixtieth of a grain of atropia every four hours during the day.

The subject of tamponing the vagina in cases of uterine hemorrhage was introduced, and occupied the rest of the time. Nearly all the members participated in the discussion. Cases were related of abortion and miscarriage, of placenta prævia, and of post-partum hemorrhage, in which it had been used.

Sponges, lint, cotton, ice, the colpeurter, and, in one case a Barnes' dilator, had been used. The general opinion was favorable to the tampon, especially in cases of abortion and of miscarriage. One of the members preferred sponges; the others the colpeurter. I was advised to not use it in post-partum hemorrhage, because we have better and more certain means of stopping it.

Some cases of interest to all were presented in this connection, but I shall not relate them, as I have occupied so much valuable space already.

The Plague in London, from De Foe.

In sending us this selection from De Foe, Dr. C. C. Vanderbeck considers that it may be of interest to the readers of the Reporter, by reason of coming from the pen of the famed author of Robinson Crusoe, as well as the evidence plainly read in the lines and between the lines of our advance in these days in hygiene.

"It was now the beginning of August, and the plague grew very violent and terrible in the place where I lived; and Dr. Heath coming to visit me, and finding that I ventured so often out in the streets, earnestly persuaded me to lock myself up and my family, and not to suffer any of us to go out of doors; to keep all our windows fast, shutters

and curtains close, and never to open them; but first to make a very strong smoke in the room, when the window or door was to be opened, with rosin and pitch, brimstone and gunpowder, and the like, and we did this for some time; but as I had not laid in a store of provisions for such a retreat, it was impossible that we could keep within doors entirely. And here I must observe again, that this necessity of going out of our houses to buy provisions was, in a great measure, the ruin of the whole city; for the people catched the distemper, on these occasions, one of another, and even the provisions themselves were often tainted, at least I had great reason to believe so. However, the poor people could not lay up provisions, and there was a necessity that they must go to market to buy, and others to send servants or their children; and, as this was a necessity which renewed itself daily, it brought abundance of unsound people to the markets, and a great many that went thither sound brought death home with them.

"It is true people used all possible precaution; when any one bought a joint of meat in the market, they would not take it out of the butcher's hand, but took it off the hooks themselves. On the other hand, the butcher would not touch the money, but have it put into a pot full of vinegar, which he kept for that purpose.

"The buyers carried always small money to make up any odd sum, that they might take no change; they carried bottles for scent and perfume in their hands, and all the means that could be used were employed; but, then, the poor could not do even these things, and they went at all hazards. Innumerable dismal stories we heard every day on this very account.

"Sometimes a man or woman dropped down dead in the very market, for many people that had the plague upon them knew nothing of it till the inward gangrene had affected their vitals, and they died in a few moments; this caused that many died frequently in that manner in the street, suddenly, without any warning. Others, perhaps, had time to go to the next bulk or stall, or to any door or porch, and just sit down and die, as I have said before. These objects were so frequent in the streets, that when the plague grew to be very raging on one side, there was scarce any passing by the streets, but that several dead bodies would be lying here and there upon the ground; and in those cases, the corpse was always left till the officers had notice to come and take them away, or till night, when the bearers attending the dead-cart would take them up and carry them away. Nor did these undaunted creatures, who performed these offices, fail to search their pockets, and sometimes strip off their clothes, if they were well dressed, as sometimes they were, and carry off what they could get." * *

A Sanitary Patrol.

A most excellent idea is that provided for in the following order, issued by the Secretary of the Treasury, under date of July 19:

"In view of the presence of an epidemic of cholera, the existence of yellow-fever, and the Oriental plague, abroad, the safety of the public health in this country demands the enforcement of rigid quarantine against the introduction of these diseases through vessels arriving at our ports. Therefore, in order to assist local authorities in the maintenance of quarantine as provided in Section 4792, Revised Statutes, the unrepealed portion of the act of April 29, 1878, and recent appropriation acts authorizing the President to maintain quarantine at points of danger, the President has determined to establish, by means of the vessels of the Revenue Marine, a national patrol of the coast of the United States, so far as it may be practicable under existing law, and consistent with the performance of the other duties confided to that service.

"You are accordingly directed to cruise actively with the revenue steamer ——— ——— under your command upon the outer lines of your cruising grounds, and to exercise especial vigilance in speaking all vessels arriving from foreign ports, directing your inquiries, first, as to the port from which the vessel hails, and, secondly, as to the health of those on board at the time of departure, during passage, and at the time of hailing; and should the information gained indicate a condition of contagion and infection in the vessel or crew, or that the vessel has left a port at which contagious or infectious diseases were prevailing, her master will be directed to proceed for examination to the outer quarantine station provided for her port of destination.

"The following regulations will be observed relative to the inspection of vessels:

"If a vessel be found with sickness on board, or in a foul condition, she will be directed to proceed to the quarantine station hereinbefore indicated, and the revenue-marine officer will immediately notify the proper quarantine officer. In such case no person will be permitted to board the vessel until the medical officers in charge of the quarantine shall have given the usual permit.

"Should the pilot or master of a vessel when hailed report cases of recent or present sickness on board, the revenue officer will not board, but will send her immediately to quarantine.

"Quarantine officers will be recognized as follows, viz.:

"Medical officers or acting assistant surgeons of the Marine Hospital Service, in charge of Gulf, South Atlantic, or Cape Charles quarantines, or any officer of said Service, on duty at any port on the interior rivers or the Great Lakes; and all quarantine officers acting under proper State or local authority.

"Herewith is transmitted a list of the ports and places where contagious diseases exist at the date of this circular. This list will be amended from time to time and furnished by the Marine-Hospital Service for your information.

"Special regulations to aid local quarantine authorities will be promulgated hereafter, should occasion require."

The Transmission of Cholera by Rail.

The National Society of Medicine of Lyons has recommended the enforcement of the following rules for preventing the transmission of cholera by railway travel in France:

1. The Mediterranean system shall at once be

divided into two sections: that of contaminated districts, and that of non-contaminated districts. The point of division between them shall be that express station which, being situated in the non-infected district, is nearest the boundary.

2. Each of these systems shall have special cars, which shall not pass the point of division under any circumstances. The point of division shall be the place of transfer of all passengers leaving or entering the infected zone.

3. Passengers coming from the infected district shall be conveyed in cars reserved exclusively for them. These cars shall be placed at the rear of the train. The cars at the head of the train shall be reserved exclusively for way-passengers. Passengers of the two classes shall be strictly prevented from entering the cars which are not intended for them.

4. When the terminus is reached, the cars that have transported passengers from the infected district shall immediately be disinfected.

5. Baggage from the infected district shall be disinfected *en route*, by fumigation with sulphur burned in stationary pans in the baggage-cars.

6. Baggage-cars which are not transferred shall, in addition to the continuous sulphur fumigation on the way, be disinfected outside, at the point of division, with a solution of sublimed chloride of zinc, or some other powerful disinfectant.

7. Hand-baggage shall likewise be disinfected, at the point of division, by exposure to the fumes of sulphur for at least twenty minutes.

8. The baggage of a passenger attacked with cholera, or who has died of the disease *in transitu*, shall, on the arrival of the train, be subjected to a special and more thorough disinfection.

Disinfecting Toulon.

"Every means of disinfection at Toulon," says the *British Medical Journal*, "has been adopted. The city is watered with a solution of carbolic acid and chloride of lime. Those who have died from cholera are buried at a great depth underground. Railway travelers are sprinkled with carbolic acid solution. The soldiery are encamped outside the town. The sick sailors are put on board the Entreprenaule to be examined; the cholera patients are removed to the St. Maudrier Hospital, which is reserved for them. The crews have been placed on vessels at anchor outside the port. The Ministers of War and the Marine have given orders to the authorities of arsenals to deliver to the civil authorities all the material for camping out that they may require. MM. Brouardel and Proust arrived on Tuesday, June 24, at Toulon, with a Ministerial decree to effect whatever measures they judge necessary for the public safety; to ordain the evacuation of entire districts, and of the city itself, if requisite. Dr. Rochaud left Paris for Toulon on Tuesday evening, also MM. Strauss and Rout, in order to continue their scientific researches. They are also commissioned to make a strict inquiry into the origin of the outbreak."

Lepers to be Put on Exhibition.

A unique variety of the moral show has been devised by a Californian, calling himself Dr. C. C. O'Donnell. He has secured two Chinese lepers, with a large portfolio of photographs of other cases, and he proposes to travel East and exhibit them. The show is in the interest of anti-Chinese immigration. Dr. O'Donnell claims that there are between two hundred and two hundred and fifty lepers in San Francisco already, and that the disease is increasing. The police authorities of the various cities in which he proposes to exhibit his lepers, at the instigation of the health authorties, have wisely decided to prohibit the exhibition.

Dr. J. M. Ambler.

It will be remembered that Dr. Ambler was the surgeon of the Jeannette Arctic Expedition, who lost his life in the pursuit of science, and whose remains were brought to this country by Engineer Melville. A brass tablet has been prepared, to be placed in the village church at Culpeper, Va., bearing the following inscription:

"JAMES MARKHAM AMBLER,

"Passed Assistant Surgeon, U. S. Navy,

"Died on the banks of the Lena River during the memorable retreat of the ship's company of the U. S. Arctic steamer Jeannette, in the year

———1881.———

"His sense of duty was stronger than his love of life.

"In memory of his noble example and heroic death, this tablet is erected by the medical officers of the United States Navy."

Items.

—There have been five importations of Asiatic cholera into this country, viz., in 1832, 1848–49, 1854, 1865–66, 1873.

—Yellow fever is reported to be prevailing on the Isthmus of Panama to such an extent that, together with an epidemic of dysentery, it has filled the hospitals both of the city of Panama and of Aspinwall.

—A grand fair in aid of the London hospitals is, it is said, to be undertaken under the auspices of the Health Exhibition. The hospitals in question are, many of them, in great need of pecuniary help.

—We learn from the "Progrès Mèdical" that a public subscription has been started in France for the purpose of erecting a monument to the memory of M. Dumas, and the Paris Faculty of Medicine will take part in the movement.

—Curci, experimenting upon dogs by trepanning and attaching a uranometer, finds that chloral, chloroform, ether, paraldehyde, and quinine, produce cerebral anæmia; morphine and nitrite of amyl, hyperæmia. Atropine in small doses has little effect; in larger doses it is rather an anemiant.

—It is announced that the San Francisco *Western Lancet* is to be consolidated with the *Pacific Medical and Surgical Journal*, and that the joint issue will be edited by the senior editor of the *Journal* and the editor of the *Lancet*. An addition to the amount of reading matter is promised, together with other new features.

—F. Hebra's prescription for baldness is as follows:

℞.	Tinct. macis,	5 grammes.
	Olei dulcis,	50 grammes.
M.		

—Professor Virchow has begun a series of popular articles on cholera in *Die Nation*, a weekly political journal of Berlin. He condemns the French for carelessness, and takes a conservative view as to the real significance of the cholera bacillus.

—The Italian Ophthalmological Association, according to the "Gazzetta degli Ospitali," will hold its meeting this year at Turin instead of at Palermo, in order that advantage may be taken of the large attendance expected at the National Exposition.

—A congress of Polish doctors and natural philosophers took place at Posen, ending on June 4. There were three hundred present, some having come from Egypt, India, and other distant parts for the purpose. The next congress will be held at Warsaw or Lemberg.

—The editor of the *Peoria Medical Monthly* states that two patients who were recently operated upon by the Heatonian method died a few days afterward from tetanus. A third patient suffered severely from an extensive phlegmonous inflammation of the whole lower limb.

—Dr. William A. Hammond announces that he has four novels written, and intends hereafter to publish two a year. He states that he would rather be a novelist than a doctor, and thinks that it is time medical men, in a literary way, give some results of their rich and peculiar experience with human nature.

—Professor von Pettenkofer, of Munich, has written an article in the *Neuesten Nachrichten*, in which he shows that a bacillus or germ is not alone sufficient to explain the causation and transmission of cholera. There must be certain conditions of season and soil which favor development. These he calls the "local and time factors."

—The Summer Surgical Course at Kiel, as we learn from the *Medical Times and Gazette*, was opened with an address by Professor Esmarch, who concluded by calling for three cheers for the Nestor of German surgery, Von Langenbeck. On the same occasion he unveiled a bust of that surgeon and one of Stromeyer.

—Dr. William Fruitnight, one of the medical staff of Bellevue Hospital, died suddenly, July 21st, at the residence of his brother, Dr. J. Henry Fruitnight, from thrombosis of the brain. The deceased was but twenty-five years of age. He was graduated from the Bellevue Hospital Medical College in 1880, and since that time has been attached to the medical staff at the hospital.

OBITUARY NOTICES.

DR. CÆSAR HENRY HAWKINS.

Dr. Cæsar Henry Hawkins, the famous English surgeon, who had been Sergeant-Surgeon to her Majesty Queen Victoria for a number of years, died in London, July 21, 1884, at an advanced age. Hawkins was born near the close of the last century. After having served for a few years as lecturer on anatomy at the school in Great Windmill street, London, he was appointed surgeon to St. George's Hospital, where he lectured on surgery, and rapidly became known as one of the most learned practitioners of Great Britain. He held this position for thirty-two years, in the meantime becoming a trustee of the hospital, until 1861, when he resigned and was appointed consulting surgeon, a post which he filled until his death. He was also for several years an Examiner in Surgery at the University of London, and a member of the Court of Examiners of the Royal College of Surgeons, of which he was twice elected President. In 1849 Dr. Hawkins was chosen to deliver the Hunterian oration before the College of Surgeons on an occasion when the late Prince Consort honored the college by his attendance. He also served at different times as President of the Royal Medical Society of England, the Royal Chirurgical, and the Royal Pathological Societies. On the death of Sir Benjamin Collins Brodie, Sergeant-Surgeon to her Majesty, Dr. Hawkins was recognized as the foremost surgeon of Great Britain, and as such was appointed to fill the vacancy in the Queen's household. He was the author of a series of lectures on tumors, published in the *Medical Times and Gazette*, and furnished a great number of other valuable contributions to that publication, as well as to the *Lancet*, and other medical journals.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

Will you please answer through the REPORTER the following: What is the best treatment constitutionally and locally for a continued series of small furuncles or boils in a well-nourished non-anæmic patient? M. S.

Vesta, Neb.

MARRIAGES.

ATKINSON—SNOW.—In Conway, N. H., by the Rev. F. A. Bragdon, Leonard W. Atkinson, M. D., son of the Rev. K. Atkinson, of the New England Conference, and Miss Isabel Snow, daughter of E. Snow, Esq., of Eaton, N. H.

McCLELLAN—PEARS.—In East Liberty Presbyterian Church, June 26, 1884, by Rev. Edward P. Cowan, D. D., Dr. James H. McClellan and Rachel May Pears, all of Pittsburgh, Pa.

NEWLANDS—BURDICK—At the residence of the bride's parents, 581 Westminster street, St. Paul, Minn., July 8, 1884. Dr. George Newlands, of Litchfield, Minn., and Miss Lizzie Burdick.

SNIDER—BACON.—In Louisville, Ky., July 10, 1884, Dr. T. A. Snider, of Sacramento, Cal., and Mrs. Chas. Bacon, of Louisville.

DEATHS.

ADAMS.—At Liverpool, England, June 19, 1884, John G. Adams, M. D.

CHILDS.—At the residence of his sister, Mrs. Lucy A. Kneeland, 578 East 145th street, New York city, July 21, 1884, Samuel Russel Childs, M. D., aged eighty-four years.

FRUITNIGHT.—In New York city, Sunday, July 20, 1884, suddenly, Dr. William Fruitnight.

MORGAN.—In Bennington, Vt., July 20, 1884, of apoplexy, Dr. E. N. S. Morgan, aged fifty-eight years, six months, twelve days.

RUGGLES.—In New York, July 18, 1884, very suddenly, Dr. Dwight Ruggles.

STANLEY.—At Wentham, Mass., July 11, 1884, William S. Stanley, M. D., formerly of Mamaroneck, N. Y., aged eighty-one years.

TAYLOR.—At Newark, N. J., on Friday, July 25, 1884, Dr. Samuel W. Taylor.

OUR ARMAMENTARIUM.*

BY C. B. NEWTON, M. D.,
Of Stofford Springs, Connecticut.

One of our greatest American surgeons said, twenty-five years ago, that "the best workman employs the fewest tools, and the best operator employs the fewest instruments, and to the man of science and taste nothing is more disgusting than an ostentatious display of such materials. The really important instruments are few in number. They are the scalpel, saw, needle, probe, forceps, and director." This is partly true, but the list of diverse surgical instruments would now, in 1883, make a legion, and have no more resemblance to each other than the plant has to the fish, or a fish has to land animals.

I think there is no country physician, isolated as we are from each other, who ever thought he had too many instruments. We have occasion to use instruments in cases which have not the remotest relation to each other. We have our own judgment in urgent cases only to help us many times. If we are supplied with the needed instruments, it gives us greater confidence to meet the indications single-handed. If we lived within a stone's throw of Tieman, or Codman & Shurtleff, a messenger might hand us the required instrument in time; but we live two days from them. There is the greatest objection to using a pair of pincers borrowed from a blacksmith shop to extract a tooth for an office patient: it may do the work, but how humiliating!—or to go there for tools to perform craniotomy, as I know was once done.

Prof. Gross may have been so skillful that with deficient instruments he may have performed the most difficult operations. So may the farmer have cut his grass with his sickle: but he would not do it the second time when given a scythe.

In our profession there is occasion for the practical application of the various mechanisms. Whether in the best adaptation of a splint to fracture, in the application of the obstetrical forceps, the skill in the introduction and use of the hand in version, in the use of the vectis or the blunt hook in the replacing of a prolapsed umbilical cord, and to the weighing of the body even, we are applying some law of mechanism relating to instruments.

I have thought there is as much need of the student being taught the practical uses of instruments of surgery—how to use them without error in their manipulation—in a series of lectures devoted to this subject, as there is in teaching them the art of preparing food for the sick. And it may be said, of course, that a student cannot know too much, of whatever sort.

Our field of labor requires knowledge far more than that of giving doses. In no profession so much as ours can general knowledge be made such extensive use of. If familiar with Latin and Greek, as well as his native tongue, with what ease, and pleasure even, he begins his anatomy, where he finds Greek and Latin descriptive names as thick as plums in an English pudding. All knowledge is auxiliary to us. The physician in his moments of perplexity, which we all have such vivid remembrances of, finds coming to his

*Read at the Eastern Hampden (Massachusetts) Medical Association.

aid like an unexpected friend a recollection; it whispers to us what our teacher said, or what we have read in our text-books. It gives us the key to the situation, and perhaps a life is saved, and added reputation for skill.

The uses of tools are largely learned in boyhood. The spoon, knife, and fork, are the first instruments we learn to handle. The boy at play is becoming skillful and dexterous with his hands. The knife is his scalpel and bistoury. His plays in mechanics are the little mimicries of his elders. The use of any tool is to be encouraged among children, which is safe for them to handle. Our dexterity in the use of instruments comes of this early practice, though it is slower of acquisition than the mother tongue. The flourish of an instrument in the hands of the operator is not pleasing. Some of you may have seen a certain operator throw an instrument over his shoulder, when used, regardless of the students behind him, and might have received their applause if not hit. This is not the best way to win laurels, but rather by its cunning and correct movement when in hand.

In the use of an instrument we find it of importance that the hand and arm be in a normal state; there should be no tremor and no haste. Bathing the arm and hand in cold water will give the hand great steadiness, remembering that especially in all minor operations time need not be considered. The students of to-day do not take out their watches as of old, and note the rapid movements of the operator's knife and saw, in order to save the poor sufferer as much as possible the torture of the operation while in his full consciousness. A sense of relief was felt when the operation was over. In this haste, how much greater was the risk of getting the flaps too long or too short; also of not securing the arteries properly, for a good knot well applied would not so certainly be made in haste. I remember well when a student the extreme suffering of a patient while undergoing an operation for the removal of a large tumor upon the cheek without an anæsthetic. I think there was valvular disease of the heart, and the surgeon refused him ether. At that time cases for its administration were more carefully selected than now. He was held by three or four stout assistants, and by being tied to the operating-table; his screams and struggles were anything but pleasant to witness, and which would now be considered a barbarism. I remember saying to a student: "How fortunate it was for the fellow that the surgeon did not cut his head off in his efforts to escape the knife, instead of the tumor." An unskillful operator would certainly have failed at least. But these scenes are over, and we may well congratulate ourselves that we have anæsthetics; that we can truly say to our sufferer, "We shall give you no pain, and when you awake we will have pleasant news to tell you." I never give ether without a heartfelt blessing to its inventor: his monument should be of granite, as high as the statue of Liberty which is to be erected in the harbor of New York, and the inscription—"The discoverer of ether, the greatest benefactor of the age."

Now with what deliberation (all that the case may demand), we proceed with our instrumental work, so that we may the more surely do it well! If a tumor, we may search at leisure for a bleeding arterial branch, halt at different stages in the operation, that every step may be well taken.

The surgeon's armamentarium of to-day is much more perfect than that of twenty-five years ago. Then the aspirator was not known: in its place was the trocar, which made an opening like a bullet-wound, with the added danger of admission of air to the cavity, which is the great source of toxæmia as a result. By this instrument we avoid this danger; one of its beautiful qualities is the ease and safety with which it can be used, either as an explorer or to drain a cavity of its fluid. It is one of the most satisfactory instruments I ever used. I used this instrument a while ago upon a five-year-old boy—it was a case of hydrothorax, resulting from pleurisy, the right cavity of chest, quantity, 1½ pints—without the slightest disturbance to the little fellow. How different this from the plunge of the trocar, with danger of permanent opening, the admission of air, and blood poisoning, and collapse of the lungs. His father placed him upon his back, in his lap, with some playthings in his hand; when I introduced the needle, all the ado he made was to tell his father that I pricked him. The needle was instantly through the sensory nerve of the skin without wounding in the slightest degree, and he took no more notice of me; of course, the track of the needle closed air-tight. I mention the case only to show its perfection over the obsolete trocar. Another instrument highly valued, and probably in the pocket of the most of the physicians in the civilized world, is the hypodermic syringe; what should we do without this little helper? We could spare a finger almost as well. What would we do in case of acute colic pain with vomiting? We say to the patient, "you will be better in about ten minutes." We don't have to stay with him all night and hear his outcries, like those of a nervous woman in her first labor.

The best mode of introducing the needle is to lift up a fold of the skin with thumb and forefinger, making thus the skin tense, the needle passed under and between the thumb and finger horizontally. I find the needle enters the skin still more easily by anointing it slightly with tallow, as the cobbler does his awl, and with Magendie's solution of morphia in the case, as its constant companion, we have all that we wish to produce a quick anodyne effect. The tolerance of the various concentrated remedies, when used subcutaneously, without inflammation of the skin or superficial tissues, opens a more extensive use of this instrument than has yet been attained. The number of remedies thus used is steadily increasing. When irritants, such as alcoholic stimulants, ether, etc., are used, they should be widely spread, little in a place; in this way, three ounces of stimulant can be injected rapidly in twenty places without inflammation. I am accustomed to press over the injected places with my fingers, moved flatwise upon the skin's surface, so that it will at once be widely diffused through the superficial fascia. This lessens very much the danger of cellulitis, which may occur from even ten drops of Magendie's solution of morphia. And I have noticed that the outer side of the arm, just below the elbow, is particularly liable to this infusion, more so than any other part that I have injected. Perhaps this is owing to greater density of structures, rather than to wounding of nerves, as is generally supposed. The best needle is the smallest which is practicable. The instrument should be well cleaned with pure water, after using, by sections, and kept pervious with its stylet. I think much of chamois leather for drying and keeping bright my needles of different kinds. It is called chamois because it is simply split sheep-skin, using the flesh side; the other side is called kid for the same reason, of which children's and misses' shoes are made. I have in use a full-sized chamois skin for rolling up a few instruments for immediate use, the ends doubled over and held by a rubber band, thus making instruments not having cases very portable, and preventing their rusting; for a rusty instrument is noticed as quickly by our little audience and as quickly criticised as we should a rusty knife and fork before us at a hotel. Nickel-plate gives an instrument a very pleasing appearance; but better than this, it keeps them from rusting. We are continually surprised to find new and polished instruments, which we had supposed well dried and cared for, covered with rust. Many of our instruments, which have been neglected and are unsightly, even if fit for use, are best restored by sending them to the nickel-plater's, and with less cost than to attempt to polish them, which is so transient, while good plating is permanent—those, of course, without cutting edges. If we act upon the prevailing theory of to-day, the cleaner the instruments the cleaner the incision, and the less danger there will be of the introduction of infectious germs which may be lurking upon the unpolished blade.

In speaking of instruments, the time is too limited to mention more than the most important ones. The obstetrical forceps should have been mentioned perhaps first in order. Of the various curvatures and lengths, the short forceps are best adapted to nineteen cases in twenty, those of best curvature to fit the concavity of the sacrum, and should be strong enough that they will not slip off during the necessary traction ; and I think it well when the presenting head has well entered the superior strait, that the forceps may be allowed to find their best position. The best evidence of this will be on the introduction of the second blade, it will easily lock with its fellow. I say allowed, because some authors teach us that they are to be applied according to the conformation of the pelvis rather than to unfavorable positions of the head; but both are to be considered. The forceps belong to a class of instruments which can hardly be improved upon. I suspect that the majority of our cases of lacerated os uteri come of the introduction of the forceps before there is sufficient dilatation of that part to allow of the passage of the head without its rupture, though sufficient to admit the forceps. Of course, another fruitful cause of this accident is rigidity of the os uteri—a state of œdema, so it seems to the touch ; some such condition as we sometimes find of the perineum. The os feels dry, smooth, and firm, like a rubber ring for teething babies. In this state of rigidity and insufficient dilatation, if one blade be introduced, then the other, and traction be made, a splitting up of the os will be apt to follow, and delivery also, but with great harm to the mother. So at the perineum we find a similar condition sometimes, rigid, smooth, dry, thickened, and unyielding.

In this condition on the descent of the head under traction, I always slip off the forceps at a moment when the perineum is at its fullest distension, in order to diminish the risk of rupture. I will say here that the perineum has torn under my hands, while trying to prevent this accident, like wet paper. It takes place in women of very delicate muscular fibre with rapid advance of the

head, as well as in robust women. Also in the matter of responsibility for this accident, I have said that it is impossible for a four-inch head to pass through an unyielding three-inch ring without rupture. The same may be said of the obstetrical forceps as of the introduction of many other very important instruments: it is surprising that they did not come into use before. Before their introduction, the only extracting force was the blunt hook, such as is now used in craniotomy. The proverb, "Omnes natura est conservativa," well expresses a truth. The world was well populated before forceps or any instrumental aid was efficiently brought into use. Nature is so wonderful a preserver of herself that a child can be born in very many malpositions; yet the obstetrical forceps have been a great blessing to woman; with these and ether an intelligent woman looks forward to her accouchment, having good faith in her physician, without fear. She knows that she can travail through its valley and shadow with less danger than could our ancient mothers, who were not so well assisted by instrumental art.

Another instrument which will never go out of use is the atomizer. Before its invention, we had nothing similar to it. It fills an important place in the treatment of diseases of the nasal cavity, throat and lungs. There was a time before the advent of this instrument, when many patients were swindled by a class of quacks calling themselves lung-doctors, who claimed to pass a probang or swab down to the bifurcation of the trachea, dipped in nitrate of silver or other solution, and some of the more ignorant ones may have thought so; but without question it went down the œsophagus. In fact, I do not think that a sponge tied to the end of a stick, saturated with strong solution of silver, could be introduced but once in the manner they pretended in the same patient, unless he was an imbecile mistaking suffocation for cure.

Of the various kinds of atomizers, Codman & Shurtleff's are the best—the one which bears their name. The rubber bellows is attached to the atomizing part by a rubber tube with an air-bulb in centre of tube, which gives a continuous jet of vapor. Also one with a long nozzle; this obviates the mouth-shield. I don't think the steam atomizer so much superior to the one worked by hand. The flame of the lamp is in proximity to the ether vapor during an operation, which is not safe. It is not so controllable, and its numerous parts make it more liable to failure when it is needed the most. Also, the hand instrument is so much more portable. A child can be persuaded to have the atomizer used, with a little coaxing, when by no amount of persuasion will they permit the use of the swab to the throat; and here in throat and laryngeal diseases is its greatest triumph. In the deeper ulcerations of the trachea and bronchi also, with what ease and satisfaction can we make local applications of the remedies! In speaking of the struggling of a little child resisting the swab, I must say that, taking into account the prostration which follows its frequent use, we lose more than we gain. To see the child's terror on the approach of the swab, the spoon, and the doctor, is not so much to me as the doubt I have that it will do the amount of good claimed for this method. In adults we have no such obstacles, of course; there the camel's-hair pencil, or in its absence a very nice brush, can be made of a strip an inch wide and four inches long, of coarse table linen, pulling out the lengthwise threads three-quarters of its width, begin to wind near the tip of the holder, then winding back a little fasten with thread, and a very handsome little broom is made, which will not scratch the inflamed surface, as will a sponge. In using the atomizer, I direct the patient to compress the bulb at every third inspiration, and if there is much debility, let an assistant operate the instrument; we thus avoid fatigue.

There is another instrument that may be considered to advantage, and one that, in my opinion, never did much good. I don't know as they have been in use ever since the advent of woman upon earth (they are mentioned by ancient medical writers), but for what we know it may be prehistoric. I allude to the pessary. I can count more failures with this instrument than any other which I have used. And when I have placed one in position, I feel a sense of guilt if the patient asks me if I think it will cure her, though we can honestly answer, "Madame, this is the usual treatment for uterine malpositions." And my experience is that the majority of these cases become chronic, and are the most intractable cases we meet of the non-fatal class. In cases where the pessary does no harm, there is an absence of inflammation, and at your next visit she may be able to say that she can wear it without inconvenience. She feels about the same satisfaction that the Irish woman did when she brought her sick child again to the dispensary: says she: "Well, doctor, I have given little Patsy all of your medicine, and he is no worse thin." I believe it to be true that the uterus, which is movable, takes positions not strictly normal, and remains so during the non-pregnant state, without harm or discomfort.

In cases of inflammation with malposition, I think the pessary always does harm from its undue pressure. Treatment for inflammation is better, and when this is removed the uterus will take its normal position unless bound down by adhesions, in which case the pessary would be of no avail. In case of prolapsus uteri, the cup pessary held in position by a stem attached to a hard rubber abdominal plate with elastic band around the body is a very useful instrument, but contra-indicated if there is inflammation or adhesions. If the uterus be not greatly prolapsed, the instrument will have to be very carefully adjusted, or it will give her greater discomfort than the disease. Of the various and diverse abuses of the uterus and the narrow way which leads to it, its welfare second only to that of her soul, I know of none greater than the wearing of an ill-fitting pessary for diseases they cannot cure or even palliate.

A CURIOUS DIET IN TEXAS.

BY C. C. VANDERBECK, M. D., PH. D.,
Professor of Hygiene, Medico-Chirurgical College, Philadelphia, Pa.

In this little article no attempt is made at an exhaustive study of the subject of dietaries; the object of the writer has been accomplished when he draws attention to some curious and unhealthful modes of eating within the borders of our Republic.

The United States of America and Territories are so extensive that we find in their limits numerous different habits and even races. In the extreme northwest, the Esquimaux; the "Wild West," the aborigines; the Pacific slope, the Chinese; the southern limits, the mixed Mexican blood. Then we are commingled with all the peoples of the earth. German is heard on every hand. Music is wafted to our ears in parks and resorts from Teutonic bands. Irish keep us lively with rumors of dynamite. The Bastile is recaptured in the New World. Havana cigars are made and imported from the alleys of our great cities. Is it any wonder then that we need no history to teach us the manners and habits of all the world. Here we can see China indulging in his smoke of opium; here we can see the fun-loving, beer-loving, sour-krout-eating German, etc. We are learning to drink beer and to love the diet of the Germans. We copy from all our foreign friends, and it is a question in sanitary science, whether foreign habits are just the thing for native-born.

But more to the point. *Among foods sometimes, but not ordinarily, eaten*, Pavy, in his work on Food and Dietetics, places the following: Human flesh, monkeys, kalong (a species of bat), lion, lynx, wolves, skunk, otter, cats as well as rats by the Chinese, porcupine, squirrel, bison, buffalo, camel, musk-ox, reindeer, horse. elephant, rhinoceros, tapir, hippopotamus, earth-hog, armadillo, sloths. Entrails of animals are eaten by the aborigines of Australia, and the Hottentots consider them to be the most exquisite eating. Zulus are fond of carrion, especially if it is well wormy. Cuckoo, parrots, ostrich, crane, buzzards, gull, pelican, swans, birds' nests, lizards, snakes, tortoises, crocodiles, frogs, toads, sharks, spiders, grasshoppers, locusts, white ants, bees, moths, caterpillars, and grubs.

Humboldt, on his return from the Rio Negro, saw a tribe eating a fat, unctious clay. This is also eaten by the Japanese, made into thin cakes. It has been found that this earth is made up for the most part of the remains of microscopic animals and plants. In the Torrid zone much of the clay eaten is mere dirt, and is of no alimentary value. Pavy says that so widely spread is the depraved appetite for earth-eating, that it is one of the chief endemic disorders of all tropical America. The victims of the practice find it almost impossible to free themselves from the habit. Children acquire it at the breast, and women will pull out pieces of mud from the adjoining walls, to appease their own appetite or to soothe a squalling brat. Servants are sometimes required in these regions to wear wire masks to keep them from putting clay in their mouths. A negro addicted to this habit is considered to be beyond all useful purposes, and seldom lives long. Children decline and die in a year or two, and dropsy appears to be the prominent cause of death. When life is prolonged to mid-life, dysentery carries them off. Cases have been seen sinking from dysentery, with a lump of clay stuffed in their sunken cheeks half an hour before death.

But I write more especially to call attention to a custom in the far south of our country, particularly in Texas. There it is a common practice for the mothers to chew the food for their children, regurgitate and spit it out, and then feed it to them. These people are firmly set in their ways, and any remonstrance is likely to be indignantly opposed. The bitch will often throw up her food, and then feed the vomit to her young; but doubtless many of my readers imagine in our own land our citizens could not practice a similar custom. Snakes and snails, rats and cats, toads and spi-

ders, are a luxury in comparison with such a diet. We scorn the diet of Australians, Zulus and barbarians; but behold, within the jurisdiction of the Stars and Stripes, a people feed on vomit and chewed food.

It may be questioned whether, outside of mere disgust, there is really any harm to health. I cannot answer just yet whether those living in those regions can see any increase of death-rate or of sickness among the children or not, but it is reasonable to suppose on theory that they do not thrive the same as if they were not thus fed, and for these reasons:

1. Food to be well received by the stomach must be *palatable*, and this is a principle even in infantile life. Some might argue that digestion, beginning in the mouth, the starchy material would be partially digested and prepared for the little one—and therefore what harm? Children as well as adults can be nauseated by impressions produced upon the tactile sense of the fingers, by an odor, a taste, or even an idea. It is not an uncommon thing to see a little infant sick with diarrhœa, sitting languidly upon the floor, made to gag and retch by chancing to pick from the floor a piece of softened bread, the wet and musty substance causing sickness at once. Certainly, for sick and delicate infants regurgitated food cannot be palatable; in fact, can it be for any?

2. It has been conclusively proven that syphilitic mucous patches in the mouth can communicate the disease. Cases are reported of such transmission from a lover's kiss, from a cigar made by a factory girl affected with these patches. Now, in this manner of feeding, there can be an element of danger in this respect.

3. Nature fully intended each individual to do his or her own sucking and eating. This is the period of concentrated foods. Is there not a possibility of too much of this? No work, no strength. One's own efforts in mastication, insalivation, and digestion are as important to strength of the digestive organs, as exercise is to the muscular system. Bulk is something in diet. Hay for horses as well as oats for thriving. Diet being right in selection, the infant has all the required organs and material for its digestion. One of the earliest instinctive acts is to seek and find food from the teeming mother's breasts. Do not underestimate the powers of the child.

The writer is well aware that in some lower animals regurgitation is a mode of feeding, as in pigeons; but anatomy teaches plainly in what animals this is a natural physiological function. It is not such in man.

Finally, the mother has enough to do to look after her own digestion, without preparing also the child's.

I trust your REPORTER will excuse the length of this article on such a subject, the apology being the knowledge of the tenacity with which this habit is held in some parts of this country, and the desire to raise a voice against it, urging those who practice there to do their utmost to educate the people to better ways.

TREATMENT OF PILES BY INJECTIONS.

BY ISRAEL B. WASHBURN, M. D.,
Of Rensselaer, Indiana.

There are few diseases that afflict humanity more painful or more common than piles. They are easily diagnosed, and may be treated with little pain, great success, and the smallest possible per cent. of danger.

Notwithstanding this fact, the disease is illy understood and has been harshly and empirically treated to a degree that has so digusted those afflicted that it is almost impossible to make them believe that we now have a treatment that is almost painless and yet a certain cure, perhaps not at the first operation, but in time.

I am aware that a majority of writers contend that piles are enlargements of the hemorrhoidal veins. Can they not be mistaken? Are they not rather an inflammation of the connective tissue? I suggest this on the authority of one who studied the disease thoroughly.

I started out to give the treatment. The physician will need an anal speculum. The one I use is a bivalve-hinge, sold by John Reynders & Co., and is marked "Collin & Co." It is simple, readily introduced, exposes about one-fourth of the rectal circumference at a single expansion, and is not very uncomfortable to the patient.

There are other instruments that may be used, but I like the one above mentioned.

In using the speculum, the patient, if a lady, may be placed on either side; if a man, on either side or back, the thighs closed, flexed upon the abdomen. If the tumors are very large or tender, it is necessary to inject two or three drachms of olive oil into the rectum to aid the introduction of the instrument. For that purpose, a No. 1 hard rubber female syringe is the best instrument.

The instrument should then be oiled with olive oil, or what I consider better is petrolatum or lard. The speculum should be introduced very gently, and as far as possible before dilating it. In dilating the rectum with the hinged instrument, it is

generally necessary after dilating the bowel one-half, to allow the instrument to partly close in order that the tumor, if there be one, may drop into the field, and show well. If the hemorrhoidal tumors are protruding, they should always be returned, if possible, within the bowel before introducing the speculum, and especially before treatment, even if the patient has to take an anæsthetic before they can be put back. Return them first.

If necessary to examine all quarters of the rectum, the speculum must be re-introduced each time the operator desires to examine the anterior, posterior, or lateral walls. In withdrawing the instrument it should only be partly closed, or it may catch and pull down a tumor, much to the discomfort of a patient.

Allingham, in his work on Diseases of the Rectum, p. 90, quotes Dr. Matthews, of Louisville, Ky., to prove the operation by the injection of carbolic acid into a pile, painful, inefficient, and that death is to be feared from peritonitis, embolism, and pyæmia.

I have used, seen used, and known of the use of the acid, in scores of cases, with no serious results following.

The principal cause of accidents alluded to by writers is the use of too strong a preparation of the acid.

If I wish to slough out a tumor, I use but one part of the acid to two of sperm oil. If to remove it by absorption, I use one to four.

The operator must not inject a syringeful, but must be governed by whether his patient is easily given pain or not. If he is of nervous temperament, five, ten, or fifteen drops will be as much as he can bear, and the operation may have to be repeated two or three times before complete removal of the tumor. In order to prepare the remedy so that the acid and oil will not separate I dissolve the acid by heat, measure the acid and oil in a minim glass, mixing both in a vial, then place the vial in a vessel containing water, and bring the water to about the boiling point; after which they will not separate.

I use a hypodermic syringe with a two-drachm barrel, with a needle about three inches long. In order that the needle be strong, the first two inches should be large with an ordinary hypodermic needle point soldered upon it. The piston should be graduated so the tap on the piston may be fixed at a point when the operator will know just how many drops of the preparation would be used in an operation.

If the patient is very nervous, weak, or easily given pain, six to ten drops of the strongest preparation will be a large dose, while the same amount of the weakest would be all that it would be necessary to use.

When everything is ready for an operation, the syringe loaded, patient in position with tumor exposed, the needle should be inserted so that the fluid would be deposited as near the centre of the tumor as possible.

The prick of the needle will pain some more than others. While one man will say he scarcely feels it, another will cry out; but that should not disconcert the operator—the remedy must be inserted in the right place, or it will fail in accomplishing the desired result.

The acid will cause some inflammation and discomfort in some cases, but generally the patient can get up and go about his business.

It is best that the bowels be thoroughly moved, and washed out with water, so that they will not move for about twenty-four hours. If the patient is nervous, and the operation gives pain, a dose of morphia might be given in order to allay pain and keep the bowels quiet the desired length of time.

But one tumor, especially if large, should be treated at once. If there are several tumors, one treatment every two weeks will soon cure them.

The above is called the "painless method" by traveling doctors, who are making large fees out of it in this and adjoining states.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE KENTUCKY SCHOOL OF MEDICINE.

BY W. H. WATHEN, M. D.,

Professor of Obstetrics and Diseases of Women.

Reported for The Medical and Surgical Reporter by Allen Kelch, M. D.

Chronic Inversion of the Uterus.

Gentlemen: This woman was sent to me some weeks ago by my friend, Dr. Greenlief, of Jefferson county. He had been called in consultation with a neighboring physician and diagnosed chronic inversion of the uterus of over two years' duration, and recommended that she come to the city for the purpose of having the uterus reposited if possible. You will observe that she is greatly prostrated, exceedingly anæmic and unable to rise from the bed. The history of the case is as follows: She is thirty years of age, had always enjoyed excellent health until the birth of her last child over two years ago. She was attended at that time by a physician who assured her upon leaving that everything was in a proper condition. She suffered considerable

pain for a number of hours, and had more hemorrhage than is usual. Upon the second day she observed an increase in the hemorrhage, and detected a large mass in the vagina. The physician was sent for, and upon making an examination, assured the woman that he had corrected the condition and that she would have no further trouble. She afterwards had no very alarming hemorrhage, suffered comparatively little, though making a slow convalescence, remaining in bed for quite a number of weeks. The hemorrhage continued from time to time for probably twelve months, increasing in quantity upon any exertion in walking or performing domestic duties. Finally it ceased for a considerable time, and she enjoyed relatively good health; it again returned, however, profusely on making exertions, and was accompanied by pain in the back and down the legs, with soreness in the lower part of the abdomen, and a sense of weight and pressure in the pelvis. She gradually grew anæmic and more prostrated until finally she was unable to walk, and has been now for several months confined to her bed with a constant elevation of temperature, and an irregular pulse ranging from 100 to 120 per minute. She is nervous, and has poor appetite, with very little power of digestion and assimilation. You observe how very much she is emaciated, and how anæmic she is.

With this history before us, we must now attempt to make a diagnosis of the condition present in this woman, but we are not able to make it absolutely certain. Nearly the same symptoms may be caused by several abnormal or diseased conditions in or about the uterus; particularly is this true in chronic inversion of the uterus, polypoid tumor in the vagina attached to the uterus, and sessile submucous fibroid and cancer of the uterus. We must, in this instance, as in most cases where there is no marked pathognomonic symptom of any particular disease in or about the uterus, regard the subjective symptoms as only indicating the necessity for a physical examination in order to perfect the diagnosis by means of the objective symptoms.

In a digital examination, we find in the vagina a pear-shaped mass about the size of the normal uterus, with the larger portion lowest. It is hard, and has a smooth surface. By pressing the finger high up along the borders of this tumor, we can feel what is apparently the non-inverted rim of the cervix uteri. This would indicate chronic inversion of the uterus, but a condition similar to this is found in rare instances where a polypoid growth lies in the vagina attached to the body or neck of the uterus with adhesions uniting the intra-cervical tissue to the pedicle of the tumor. The differentiation between these two conditions is to be made by pressing the finger far behind the tumor in the vagina, up against Douglas' cul-de-sac, while the other hand presses down deep into the abdomen, just above the symphisis pubis. If this tumor be chronic inversion of the uterus, then we will find there is no uterus in the normal position, and all that can be felt with the hand above is the rim of the inverted uterus. But if it be a polypoid growth attached by adhesions to all parts of the cervical canal, then we will find the body of the uterus in its normal position. Were we to fail in making a diagnosis by this means we might introduce a finger into the rectum, press down upon the abdomen above the symphisis pubis with the other hand, and by this means discern the presence or absence of the uterus in its normal position. Failing in this, or still being uncertain, we might go further; dilate the anus, introduce the hand gently into the rectum, and carrying it up, bring it directly in contact with all the structures of the pelvis, having only the thin rectal wall intervening.

In chronic inversion of the uterus acupuncture gives pain, while in a polypoid growth it does not give pain.

In this case we can determine without resorting to all these means that this tumor is constituted by chronic inversion of the uterus, and this condition, no doubt, has existed since the birth of her last child.

It is possible for the uterus to become inverted at other times than after labor, but by no means is that common. The uterus cannot become inverted unless there is a relaxation of the muscular fibres with drawing down on the walls from below or a pressure from above.

After labor it may result from drawing down upon the placenta in an effort to remove it, or it may result from the general relaxation of the uterus after the placenta has been removed. In the unimpregnated condition it may result from the attachment of a fibroid polypus or a submucous fibroid to the walls of the uterus. There are a few instances of spontaneous inversion.

Having now made the diagnosis of this case, we will consider for a moment what would be the result were we not to interfere with it by remedial medicines and surgical means. First, however, let us consider what the principal danger is, that produces serious results in inversion of the uterus. Hemorrhage is the symptom above all others that is harmful. A woman may have chronic inversion of the uterus for a considerable time, occasionally for many years, without any alarming hemorrhages; but this is so exceptional that we can seldom expect such happy results, and usually the hemorrhage is so profuse that the patient becomes rapidly prostrated and anæmic, and will finally succumb by exhaustion, her digestion and assimilation becoming seriously impaired, just as they have in this patient.

Sometimes, however, women suffer from profuse hemorrhage, severe pains in the back and abdomen, heavy pressure in the pelvis, producing great exhaustion; yet the hemorrhage gradually ceases, the anæmia disappears, and they begin to improve, and finally get comparatively well. In rare instances they live a long life without further trouble, the uterus undergoing atrophy, and growing smaller and smaller; yet in most cases there is eventually a recurrence of the symptoms.

We now come to the important part of this subject, viz: what are we to do with this patient; she is now in such a weakened prostrate and anæmic condition, and so extremely nervous, with several degrees of fever, that no operation for the purpose of repositing the uterus could for the time being be resorted to. So that in this case our first duty is to temporize, and to control the hemorrhage, while at the same time an effort be made to improve her nutrition by giving good

nourishing and easily digested diet, by allowing the rays of the sun to shine upon her, and by giving rich tonics. The hemorrhage may be controlled by keeping her quiet in the horizontal position and by the injection of some concentrated astringent, such as alum, tannic acid or acetate of lead; and if this does not succeed, by exposing the uterus by means of Sims's speculum and then applying some caustic to all its surface—mineral acids, nitrate of silver, carbolic acid, etc.—after which use some solution that would neutralize any superabundance of the application, then wipe the parts dry, and place around the uterus pledgets of absorbent cotton to protect the vaginal walls.

By some of these means hemorrhage can be controlled, and finally the patient regains sufficient blood and strength to place her system in a condition that will enable her to tolerate an operation. Then what are we to do? Why of course reposit the uterus, if possible. And how are we to do this?

There was but little known in regard to the exact pathology and proper treatment of chronic inversion of the uterus until the present century, and but few successful cases of reposition until after the middle of the century. But little was written on the subject until the time of Ambroise Paré, about the middle of the seventeenth century. The old method of treating these cases was by the amputation of the uterus. It was not believed that it could be restored to its proper condition by any possible means; but we now know that there are but few instances where it is impossible to succeed in this operation. It may be reposited by gradual or by rapid reduction—in the first instance, by elastic pressure, with vaginal stem and cup; or by elastic pressure, with vaginal water-bags with taxis, or by vaginal water-bags alone.

Gradual reduction should, in nearly every case, be attempted before resorting to rapid reduction, for the reason that it is often successful, and is always less dangerous. This plan of treatment may be persisted in for days, and sometimes for weeks even, with impunity, the patient's condition being the index of the continuation of the treatment.

If, however, failure result from this method, we then resort to rapid reduction. Having brought the patient's system into a proper condition, we relieve the bowels and the bladder, then placing her under the influence of an anæsthetic the operation is begun with three or four good assistants.

A great many methods, differing one from another in minor points, have been practiced by different authors, each, however, generally similar in principle. We will not have time to-day to go into the details of the operations by the various methods, and I intend to call your attention to a means that has recently suggested itself to my mind, and which I shall avail myself of in this case when she is in a condition to be operated upon. As I have just hinted, in all the methods suggested and practiced for the reduction of chronic inversion of the uterus, it is necessary to use pressure and counter-pressure; in fact, we could hardly imagine how the operation could be otherwise successful. Various means of applying pressure and counter-pressure have been devised, and in the effectiveness with which these are applied consists chiefly the superiority of one operation over another. The pressure is usually applied directly by the hand or indirectly by means of cup-shaped instruments that fit over the fundus of the inverted organ. The counter-pressure is applied through the abdominal wall just above the symphisis pubis or against the uterus, or one or two fingers are introduced into the rectum and hooked over the uterus into the ring of the cervix.

Thomas operates for inversion by abdominal section, and after dilating the cervix, applies the counter-pressure directly to the neck.

The operation to which I will call your attention to-day differs only from other operations in the application of counter-pressure; this is applied from the vagina upon the non-inverted cervix while the pressure is being used. This can be done by introducing several large silver or silk sutures deep into the non-inverted cervical tissue, or by seizing the lips with properly-constructed seizing-forceps. By pulling upon the sutures or the forceps while the pressure is being applied, we have a counter-pressure entirely within our control. Besides, the force is so applied as to assist in dilating by pulling the cervix outward and downward over the body of the fundus. The principle of this procedure is apparently correct, though I have had as yet no opportunity to test it in practice.

If this means of reduction has been suggested or practiced by any one, I would be pleased if the profession would correct me and point me to literature on the subject. The operation would certainly be an improvement over any previously practiced, unless the sutures or the seizing forceps fail to hold in cervical tissue till the reposition is accomplished.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, February 7, 1884.

The President, R. A. Cleemann, M. D., in the chair.

A Year's Work in Ovariotomy.

Dr. Wm. Goodell read a report of his cases of ovariotomy during the past year. Of these he had twenty-five, with seven deaths. Eleven of them were performed in the private rooms of the Hospital of the University of Pennsylvania, with one death; ten were operated on at their homes, with five deaths; and four at his private hospital, with one death. He attributed the majority of these deaths to three causes:

First. That he made it a rule never to doom a woman to certain death by refusing to operate on her, however forlorn the hope of her recovery might be, and three of these fatal cases were very ill indeed at the time of the operation, from septicæmia and purulent cysts.

Secondly. That the women of this country being unwilling to go to a hospital, either insist on being tapped, which increases the risks of the radical operation; or else postpone the operation until the tumor has become very large, adhesions

have formed and the health has become greatly undermined. Out of his twenty-five cases he had but eight without adhesions, and one of these, a case of double ovariotomy, died at home, he not having seen her or treated her after the operation.

Thirdly. That five of his fatal cases had been operated on at their own homes, which were so distant that he was able to see but one of them after the operation, and she did not rally, but died in eight hours, from the shock of the removal of an intra-ligamentous cyst universally adherent. The fatal case at his private hospital was one of pelvic abscess bursting into the bladder. The operation was not a difficult one, although the lower portion of the cyst had to be separated from the two layers of the broad ligament by which it was enveloped. The sole fatal case out of eleven performed at the Hospital of the University was due to hospitalism. This he deemed a good record, for the building is used as a general hospital, with many railroad accident cases and suppurating wounds. In this hospital he always operated in one of the private rooms, where the patient was kept until all danger was over.

Out of the twenty-five cases of ovariotomy, there were twelve in which both ovaries were removed. In all these cases the second ovary was positively diseased. Yet with a larger experience, he (Dr. Goodell) was becoming more and more inclined to remove both ovaries in all cases of malignant degeneration of one ovary, in all women who have passed the climacteric or who are approaching it, and in all cases complicated with fibroid tumor of the womb.

Finally, he referred to the fact that some ovarian cysts, although they may appear to the eye benign, show from their subsequent history that they are malignant, the woman dying a few months later from carcinoma of the pelvic organs, or at the site of former adhesions. Very unfortunately there are no diagnostic criteria to indicate the character of such a cyst.

Dr. B. F. Dawson, of New York, upon invitation by the President, spoke of the English ovariotomists, and alluded to what he had himself seen while on visits to England, as to very desperate cases being operated upon. His own late experience had been so good that he was inclined to attribute it, as well as the good results of the English operators, to absolute painstaking in the most trifling details, with absolute cleanliness; not simply antisepsis, but the utmost care throughout every step of the operation. Among other things, a very large number of hemostatic forceps are used to secure each bleeding point the moment that bleeding commences. His own last six cases of laparotomy, performed this winter, two of which were very desperate in their character, have been successful, and the results he felt were largely due to the avoidance of any preventible hemorrhage, and great care through all stages of the operation to prevent blood or fluid from the cyst escaping into the peritoneal cavity. This care is exercised throughout the "toilet of the peritoneum," and he always uses a flat sponge, as does Mr. Wells, inside of the abdominal walls, upon the intestines while introducing the closing suture, which is removed only when it becomes necessary to do so to twist the last wires.

He always uses napkins to fold over the edges of the abdominal incision, to prevent the oozing from the edges escaping into the peritoneal cavity or soiling the operator's fingers. He also enfolds the cyst in towels as it is withdrawn from the cavity, to guard against even a trace of fluid soiling the intestines or wound. He clamps the pedicle temporarily when possible, and places a napkin under the clamp before dividing and cauterizing it. Every adhesion that shows any risk of bleeding is cauterized as soon as it is separated, even when ligated. Douglas's pouch, especially, is sponged out until the sponges come away absolutely clean. In a recent very desperate case, one in which Dr. Emmett expressed his sympathy with him as to its almost certain fatality, the operation occupied two hours and forty minutes, owing to painstaking observance of the above details, and although half of the uterus was removed and adhesions were numerous, calling for many ligatures and frequent use of the cautery, yet convalescence was uncomplicated and speedy.

Dr. Goodell had operated successfully in patients aged respectively sixty, sixty-one, sixty-two, sixty-four, sixty-five, and sixty-seven years, and some one in this city had a successful case in a patient over eighty-three. Dr. G. had once operated upon a patient seventy-six years of age, of a long-lived family. This was before the days of antisepsis, and the patient died. He believes that minute attention to details is the chief element of success. One important point is to make the abdominal incision sufficiently large to see every adhesion as it is separated, and to ligate or secure immediately every bleeding point. This requires a courage which it took him years to attain. He always observes Spencer Wells's method of placing a flat sponge beneath the abdominal walls when introducing the closing sutures. He does not like wires, but always uses carbolated silk sutures, each eighteen inches long. After all have been placed, the ends are twisted together into one strand on either side, and caught in the bite of a pressure forceps. The lips of the incision are then widely separated and a final search is made for any oozing, leakage, or accumulation of serum. This final toilet of the peritoneum cannot be made when wires are used. He now believes in the use of a drainage-tube, but he had hard work to bring himself to the point of accepting it, as he still looks upon the tube as a foreign body, a necessary evil. He had once seen death caused in a healthy man by the simple perforation of the peritoneum, without wound of the intestine, by a small stiletto, and this had made him fearful of the effect of the presence of a drainage-tube. But he now considered that the peritoneum in the case of an ovarian cyst has, by thickening and attrition, lost much of its vulnerability, and does not resent slight causes of irritation. He occasionally resorts to the actual cautery at a black heat to stop bleeding from torn adhesions, but he prefers the pressure forceps, the ligature, or the application of Monsel's solution. He thinks there may be some truth in Dr. Smith's idea concerning the effect of the low temperature of the operating and of the convalescent room. He was struck with the absence of ill results in one operation in London by

Dr. Bantock, of which he had been a spectator. The day was cold, damp, and foggy, and the operating room was chilly, the windows being open; but the patient promptly recovered. One case of his own in which the extreme emaciation and prostration of the patient forbade postponement was operated upon in severe winter weather; the steam pipes at the hospital had been frozen over night, and although they had been thawed out, the temperature of the operating room was only 54°. In this case the cyst had contained colloid matter and had burst spontaneously; all that could possibly be removed was scooped, sponged, and washed out. Much remained behind, yet the patient recovered, and afterward became quite fat. This operation was performed three years ago; both ovaries were removed, but another tumor can now be discerned in the abdomen. The patient being fat and also very sensitive, it is not possible to determine accurately its character, but he hopes it is a pedunculated fibroid of the uterus, and not a malignant tumor.

Dr. Dawson requested Dr. Goodell to give his opinion respecting the management of the drainage-tube, and of the importance of the spray.

Dr. Goodell when operating in private houses has begun to dispense with the spray. Carbolic acid spray poisons some patients, and he, being afraid of it, only uses it when he does not consider it safe to omit it, as, for instance, in a general hospital or when there are many spectators present. Year before last he lost one patient from its use; she had contracted kidneys. Only last week, in a case operated on in the Hospital of the University, the patient was profoundly affected by it, and was with difficulty restored by means of digitalis, stimulants, etc. When he omits the spray, he uses the drainage-tube more frequently. If he finds in Douglas's pouch, after the sutures have been placed, and the sponges removed, two or three drachms of bloody serum, and the source of this oozing cannot be found, he inserts a drainage-tube; and he also uses it in all cases in which there has been peritonitis, or where septic symptoms are present from a purulent cyst. Over the mouth of the tube he springs a piece of rubber sheeting, which is folded over a sponge squeezed out of a five per cent. solution of carbolic acid. The sponge is examined and squeezed out every few hours, and the tube moved slightly, to clear the openings and allow any accumulation of serum to escape. As soon as a moderate amount of serum escapes without any tinge of blood, the tube is removed. This generally happens within forty-eight hours, but in one case it was necessary to allow it to remain five days. He never irrigates the abdominal cavity, but he sometimes introduces the long nozzle of a hard rubber syringe into the tube, and draws out any serum that may have accumulated. When he operates in the country, and leaves the patient in the hands of the family physician, he tries to avoid the use of the drainage-tube as much as possible.

Dr. Dawson had given some attention to the question of the drainage-tube. In New York two deaths had lately happened after ovariotomies, and in each case the surgeon had ascribed the fatal termination to the too early removal of the tube. Soon after these unfortunate cases he had operated and had been obliged to use the drainage-tube; on the second and third days after the operation the serum exuding from the tube was bloody. On the fourth day it was pure serum. The patient was doing well, and Dr. Dawson concluded to let well enough alone, and, with the result in the other two cases before him, allowed the tube to remain. He used a wire with a pledget of cotton attached to the extremity, to soak out the accumulated serum, and continued to use fresh pieces until they came away clean. The tube was evidently being walled in by a deposit of lymph around it. On the sixth day, after finding very little serum, the last pledget of cotton brought away a little yellow spot that might have been either lymph or pus. That night he discovered another trace of the same appearance, and the microscope showed it to be pus. The next day the discharge was fetid. A saltspoonful of iodoform was put into the tube every time it was cleaned, and on the tenth day it was removed and a roll of absorbent cotton saturated with iodoform was put into its place. This was replaced in a few hours with another, until all signs of pus ceased. The opening closed in forty-eight hours. The patient recovered. He would like to ask if Dr. Goodell had ever regretted removing a drainage-tube too early. Is a drainage-tube more of a foreign body on the third or fourth day than it is on the first?

Dr. W. H. Parrish had recently performed abdominal section for the removal of a fibroma of the uterus. In this case he used a drainage-tube, although he was not able to pass it down into Douglas's pouch. On the third day he noticed that the serum escaping from the tube was cloudy and had a slight odor. On the fourth day the odor was quite objectionable, and as the tube had evidently become separated from the abdominal cavity by the formation of a canal of lymph around it, resembling in appearance diphtheritic membrane, he decided to withdraw the tube. He washed out the canal with a two per cent. solution of carbolic acid. The canal soon closed, and there was no return of the offensive odor.

Dr. Goodell could not recall the loss of a case after the removal of a drainage-tube. He has had, however, a number of deaths while the tube was still in position, but that meant simply that the cases were complicated and difficult ones. Was not the tube itself the cause of the pus in Dr. Dawson's case? Air containing germs was, of course, admitted into the tube in the cleaning-out process, and the germs would cause decomposition of the lymph. Might not also the tube, acting as an irritating foreign body, cause pus? He introduces a stitch in such a manner, beyond the drainage tube, as to make tension of the skin around the tube, and this closes the opening as soon as the tube is withdrawn. He has occasionally followed the removal of the glass tube, by the introduction of a rubber one of smaller calibre; but he has discontinued this practice, believing the glass tube to be the least irritating.

Dr. W. H. Baker reported for Dr. Walter F. Atlee, a case of

Abdominal Section.

Mrs. E. C., of Erie, Pa., was brought to this city by Dr. Edward Cranch. She was forty-five years of age, married, but had had no children.

Her menses were regular and very abundant. She was a stout woman in excellent health. Four years ago she first noticed the tumor in the centre of the abdomen. Dr. C. reports that the probe enters the womb the normal distance only.

Diagnosis. — A multilocular cyst with thick walls and very glutinous liquid, or a fibroid tumor of the uterus. The sense of fluctuation was not distinct.

Operation.—February 4. After the usual preparation, cut down, found a solid tumor, opened it, took out as much as possible of the contents, and got out the envelopes. The incision was about five inches in length. The tumor grew from the fundus of the uterus. It was transfixed, tied, and dropped. The patient never rallied after the operation, and died on the 6th of shock. There was no hemorrhage. The operation was all over in twenty-five minutes.

Dr. R. P. Harris saw the patient prior to, and assisted in the operation. The lady had an appearance of health, was quite robust. and there was nothing in the contour or expression of her face indicative of ovarian cystoma. In a conversation with her sister and family physician, he learned that the diseased growth was first noticed by this sister, who remarked upon the central prominence of the abdomen of the patient, who was at the time lying on her back on the floor, engaged in playing with a little child. When the attention of the patient was directed to the fact that her abdomen presented a central elevation, even when flat upon her back, she readily detected the existence of something abnormal. Dr. Harris remarked to the physician that the history of the case indicated the existence of a tumor at the fundus uteri. When the morbid growth was exposed it did not present the appearance of an ovarian cyst; neither did percussion indicate the presence of fluid prior to incising the abdomen, except by a surface wave. There was no wave transmitted from hand to hand. The surface wave was found due to some ascitic fluid. As no fluid escaped by tapping, the tumor was opened, and its contents torn away in pieces, so as to reduce it sufficiently, when it was drawn through the wound, ligated at its union with the fundus uteri, and cut away. During the shelling process, a considerable loss of blood took place, and the appearance of the patient was that of great prostration. The tumor had no pedicle, being sessile in its attachment to the uterus.

Tracheotomy in Diphtheritic Croup.

The *Med. Record*, June 14, 1884, says:

At a series of meetings recently held by one of the sections of the Academy of Medicine to discuss the treatment of diphtheritic croup, the large numbers in attendance and the close attention paid to the speakers showed the great interest taken by the profession in this subject. One noticeable feature in the discussion was the very general skepticism as to the utility of solvent inhalations in the destruction of the false membrane. There was exception taken to this sentiment, however, by a distinguished gentleman present, who thought that by a faithful use of the spray, about one in eight cases might be saved. There is apparently some uncertainty attending this mode of treatment. The pseudo-membrane is composed of several different elements, which may yield relatively to different solvents; but as we do not know in any individual case which of the component parts of the membrane preponderate, we cannot be sure that the best inhalation is in use. This is possibly an explanation of the fact that good results have been claimed for such widely differing solvents in different cases. It is also uncertain how much of the inhalation actually reaches the larynx in a young child. The atomizers in common use do not throw a very strong spray, and few children can be kept near enough to receive the full benefit of what is thrown out. Most physicians agree that a moist atmosphere, in which fresh air is not excluded, is desirable in the treatment of croup. In one of the papers, the internal administration of corrosive sublimate in frequently repeated doses, was recommended as promising great results. These good results, however, have not as yet been fulfilled, and probably all will agree, that despite the best medicinal treatment most cases of diphtheritic croup will die if no operation is performed. The important question for the physician is, whether the operation itself affords enough chances of success to warrant its frequent performance. The oldest statistics are rather disheartening; but in the past two or three years much better results have followed the performance of tracheotomy. It is of some interest to inquire the cause of this improvement in results. Is it due largely to fortuitous circumstances, or has a more intelligent application of our art not been been a factor in its production? Many observers consider that the type of diphtheria has changed somewhat in the past few years. There is less manifestation of septic blood-poisoning that produces heart-failure, nephritis, and so many fatal results after the obstructive laryngitis has been relieved by tracheotomy. It is not unreasonable to suppose, moreover, that the treatment may have assisted in altering the type of the disease. The free use of alcohol, by preserving the action of the heart, and the large doses of tinct. ferri chlorid., which maintain the integrity of the red blood-corpuscles and assist the engorged kidneys, have certainly been factors in changing the mortality of diphtheria. It is also only fair to suppose that the better results of tracheotomy are partly due to our learning more about the opera-

tion and the after-treatment. Certainly the brilliant results recently attained in ovariotomy are not due to any change in the nature of ovarian tumors, but to a scrupulous attention to every finest detail in the operation and its after-treatment on the part of the surgeon. We do not mean to affirm that tracheotomy is performed more skillfully now than formerly; but by not delaying the operation until the child is moribund, and by paying more attention to the after-treatment, the mortality has been lessened. In fact, if the operation is to be performed, the sooner it is done the better the prognosis.

Morell Mackenzie stated, in a lecture delivered on diphtheria in this city, that when the dyspnœa was sufficient to cause much recession at the epigastrium, the operation should not be delayed. If this rule were promptly followed, we think it would result in a saving of life. Granting that occasionally a case might have recovered without a tracheotomy, we know the vast majority die if not operated on; and the operation had better, in rare instances, be performed without absolute necessity, than that in the great majority of cases its dangers be increased by too long delay. There is room here, as always, for intellectual individualizing. While no absolute rule can be laid down, and unnecessary operating is always to be deprecated, we think that in tracheotomy, of all operations, delay is dangerous. After the operation a physician or trained nurse should be in constant attendance. This is one of the most important features of a case. Many children have died who could have been saved by a little intelligent handling at this time. The tube must be kept absolutely free from mucus and shreds of membrane, by frequent cleansing in a disinfecting fluid. In many cases this not done with sufficient thoroughness. We have seen cases in which both ends of the tube were clean, but at the bend the calibre was largely occluded by thickened mucus. The attendant must have sufficient intelligence to recognize any such cause of embarrassed breathing and quickly relieve it. At the same time the supporting constitutional treatment of diphtheria must be continued. Within the past few years physicians in this city have saved one-fourth, one-third, and even one-half of their cases after tracheotomy. Even if the child do not recover, death is often rendered easier. There is no greater triumph of art than to see tranquil breathing take the place of agonizing dyspnœa, as the result of an operation. Very early age, while not favorable to tracheotomy, does not preclude its performance, as an infant in this city recovered at the age of eleven months. In concluding we would urge physicians to be ready to operate themselves. A careful, practical study of each of the steps of the operation upon the cadaver, and a steady hand, should enable one, in case of necessity, to perform a tracheotomy. Invaluable time is often wasted in searching for a surgeon. A few hours, or even minutes, may make the difference between life and death. We predict a brilliant future for this operation.

The Preventive Inoculation of Hydrophobia.

The *Medical News*, June 14, 1884, says:

The cable has recently brought to this side of the Atlantic news that M. Pasteur had discovered, isolated, and cultivated the virus of hydrophobia, and made protective inoculations with it. Immediately, the medical journals repeated this announcement, and the public prints gave it a warm welcome, and spoke of it as a great achievement, full of promise for suffering humanity. Medical men, too, have been interviewed by newspaper reporters, and, on the strength of the meagre and imperfect abstract which the cable had furnished to the daily papers, have expressed an unqualified approval and endorsement of Pasteur's views.

We have delayed our comment until after receipt of the paper of M. Pasteur, read before the Academie de Medécine, May 20. This is now at hand, and demands, we think, a little different handling from what the previous account has received, and of a sort which the possibility of Pasteur being misrepresented in this would have hardly warranted.

The points of M. Pasteur's paper are as follows: The protective power of inoculations with attenuated virus is an established fact. The virus of rabies is attenuated by passing it by successive inoculations through the monkey. It is increased in virulence by similar passage through the rabbit or guinea-pig. In either case it can then be communicated to the dog in its modified state of virulence, either greater or less than original, producing in one case certain death, in the other protection. The plan of action proposed is to take the virus from a rabbit dying after inoculation at a period somewhat longer than the shortest (which he assumes to indicate the greatest virulence) and inoculate this successively in other rabbits, inoculating in the first instance from it, and in turn from each of the series of rabbits, a dog. The effect, Pasteur asserts, will be to render the dog refractory to the rabies which occurs "on the streets," that is, to the natural as contrasted with artificial inoculation.

Pasteur next asserts: "By inoculations of the blood of animals, I have succeeded in simplifying very much the operation of vaccination, and in procuring in the dog the most refractory state." He expresses the hope that he will be able, by the application of his theory, to secure immunity in animals after they have been bitten. Finally, he says he would have been happy to have published this announcement only after his conclusions had been "controlled" by some of his colleagues, but for the lack of sufficient material, and that he has asked the Minister of Public Instruction to appoint a commission to test the results of his experiments.

The scientific and humanitarian importance of this announcement is very great, and, being coupled with the positive assertion of Pasteur that it furnishes an "infallible" means of preventing and curing hydrophobia, there is no wonder that numberless persons have applied to M. Pasteur and expressed their willingness to be inoculated with the modified virus which causes rabies. But, as the reaction which follows upon the dispelling of an illusion is all the greater the higher the illusion has raised the hopes of mankind, it may be worth while to call the attention of our readers to certain facts which ought not to be out of mind for an instant when weighing the claims of this promising announcement.

In the first place, it ought not to escape the notice of the careful observer that what Pasteur proposes in his paper is not a strict application of his own theory. He claims that passage through monkeys weakens the virus, while passage through rabbits strengthens it; and then he proposes protective inoculations with virus taken from rabbits, which is more virulent, not virus from monkeys, which is attenuated. In the second place, it will be noticed that he does not assert that he has in this way secured immunity against rabies a single time. He says he has *simplified the operation of vaccination by inoculations with the blood of animals*, and so has produced the most refractory state. He has not made, and does not dare to suggest, the application of his theory to the protection of human beings. And for animals he only hopes its application may prove effective to save after a bite has been inflicted. The request for the appointment of a commission to test the value of his hopes, indicates that M. Pasteur is willing to have it tested, but it would be a mistake to suppose it adds to its claim upon the acceptance of others *before the test is applied*.

There are other serious flaws in the argument of this paper, but we have not time now to point them out. We pass to some more general considerations as to the position claimed by M. Pasteur and his supporters in relation to this subject.

M. Pasteur has done a great deal to advance the study of what are called disease germs, but he has not had such confirmation of all his assertions as to warrant the acceptance of a strange statement from him before it has been tested and corroborated by others. In a variety of matters he has made extravagant claims of discovery, which have not borne the test of time. In regard to hydrophobia, it is not long since he made an announcement, as positive as this last one, which was very soon shown to be utterly erroneous. Even if this were not the case, one might look with some distrust upon the statements now made in regard to the curious weakening and strengthening of the virulence of the assumed virus of rabies by respective inoculations into rabbits and monkeys. In regard to this matter, the assertions of Pasteur lack the essentials of scientific accuracy. We have not yet been told the reason for calling rabid the dog from which he got the virus he first used. No one but Pasteur has seemed to show that this virus resides where Pasteur says it does—in the brain especially, and with peculiar virulence. On the contrary, as Pasteur does not appear to know, many other parts of the body, solids and fluids, have been inoculated with as great degree of success as he claims for his inoculations with the virus taken from the brain, where he says it can be gathered in "perfect purity." Further, he, and those who follow his lead, find it convenient to ignore utterly the inoculation-experiments of such excellent observers as Hertwig, Wright, Galtier, Paul Bert, and Colin, which show that, whatever it may be which is produced by the inoculations of brain substance, this does not succeed as invariably in the hands of others as it does in those of Pasteur; that, when it does succeed, the result does not differ from what can be effected with many other matters from various parts of a subject supposed to have rabies, or from similar parts of subjects beyond suspicion of it; and that the result is probably a form of septicæmia, not rabies at all.

For a few years Pasteur, whose attention was accidentally attracted to this subject in the Academie de Médecine of Paris has been experimenting upon it. If he has ever produced what can with security be called rabies by his inoculations, the record of these experiments is wanting. If he has a well-defined idea of what rabies really is, he has never yet made it public. On the contrary, he has formulated in another place a sort of definition which is elastic enough to permit him to affirm anything produced by his inoculations to be what he was after. "Nothing," he has said, "is more varied than the symptoms of hydrophobia. Each case of hydrophobia has, so to speak, its own special ones" (*les siens propres*).

This is not the way to get at a truth so obscure as the nature of hydrophobia. And we think it a duty to warn our readers against too hasty an acceptance of this recently cabled announcement of Pasteur, or too sanguine a trust in the saving grace of a virus attenuated by passage through monkeys. It may be all so; but this newcomer has such a questionable appearance that we may not be accused of being too skeptical if we wait the report of the commission appointed to consider the subject.

A New Method of Reducing Dislocation of the Hip.

In the *Transactions* of the Vt. Med. Soc., Dr. S. J. Allen writes:

"One day in the month of March, 1841, at which time I was a student of medicine in the office of John L. Swett, M. D., of Newport, N. H., I was riding in my sleigh about three miles south of the village, and passing a house situated some six rods from the road, I heard an outcry. Looking in the direction of the alarm, I saw a woman, Mrs. Perry by name, who, in stepping from the door had slipped and fallen upon the ice-covered ground. Hitching my horse, I walked rapidly towards her. As I came near, two men came out out of the house, and, raising her erect, assisted her inside.

"Grasping the leg with my right hand and the thigh with my left, I flexed the leg upon the thigh at right-angles with the body. The old lady, for thus I considered her, although but forty, complained that I hurt her badly, and somehow the limb became fixed in the position, and could not be moved. It seemed locked, and could not be moved without considerable force and pain. I immediately stepped upon the bed, and standing with her limb between my own limbs, and placing the dorsum of her foot against my nates, with my right hand under the bend of her knee, I lifted her hips from the bed, holding her steadily in that position less than half a minute, when the head of the bone slipped into the socket, accompanied by that peculiar audible shock which so delights the surgeon's ear. She immediately exclaimed, 'I am well, I am well.' Of course it was unnecessary to send for Dr. Swett then, as the patient was 'all right again.' Then from my directions the horse was returned to the stable.

"July 16, 1872, I was called in consultation with Dr. Sperry, of West Hartford, Vt., in the

case of a French Canadian, Lewis Baumhoe, by name, a section hand on the Central Vermont railroad, who, while helping to carry a track rail, fell and struck on his right knee, the rail slipping from his shoulder, and falling upon the sacrum, dislocating the right femur upon the dorsum ilii. When I arrived at West Hartford, Dr. Sperry asked me if I had my pulleys. I answered, that I had *the* pulleys that *the* Almighty furnished me with. Said the doctor, 'You can't set the legs *without pulleys*.' I answered that I could try. After the patient was chloroformed, the whole muscular system being relaxed, I stepped upon the the bed, and flexed the leg upon the thigh, with the thigh at right-angles with the body, and, placing his foot between my legs, with its dorsum against my nates, and my right arm beneath the flexed knee, I lifted his hips well from the bed, and held them immovable in that position less than one-half minute, when the head of the thigh bone returned into the socket with the usual audible sound. The reduction was accomplished so quietly that the doctor, who was standing at the patient's head, with his inhaler in hand, did not notice when it occurred, nor did he comprehend the method used, and at first questioned the fact of its having been reduced.

"By this method, the lower part of the body is lifted well from the table or bed, and held immovable. The weight of the hips and opposite leg rotates the body outwards, producing just sufficient abduction and distension to quietly draw the head of the femur through the slit in the capsular ligament, and direct it into the acetabulum. By this method no further violence is done to the soft parts about the joint; the head of the femur being drawn directly back through the rent in the capsular ligament without increasing its laceration in the least, which no other method *can* claim.

"One word in regard to other forms of dislocation of the hip. The dislocation into the ischiatic notch is a mere continuation of the dorsal form; the head of this bone being thrown simply further from the socket, it is evident that this method will quite as readily reduce this form of luxation.

"The foregoing cases, it will be observed, are all cases of dislocation of the dorsum ilii, but at the same time we should remember that luxation on the dorsum is the type of all dislocations of the femur, and that before reduction is accomplished in the other and rarer forms, the head of the thigh bone must be thrown on the dorsum before it can be returned to the acetabulum. Indeed, it is not uncommon for the head of the femur to be changed from one position to the other several times during the manipulations before it can be reduced by the method of Dr. Nathan Smith. In my method the *automatic* principle is evident. The patient, being placed and held in a certain position, sets his own dislocation, thereby making him 'particeps criminis' in case of suit for malpractice."

The Treatment of Cholera.

From the host of remedies and suggestions that are now deluging the European medical press, we select the following from Dr. Henry A. Rawlins, in the *London Med. Times*, July 12, 1884:

The man suffering from cholera has been suddenly deprived by diarrhœa of an enormous quantity of the fluid part of his blood. This loss is one of simple transudation, increasing as the powers of life decrease. This *sudden* loss produces intense prostration, and renders the heart powerless to perfect the circulation. The body, thus deprived of oxygen, speedily runs into decomposition, even before life is extinct. Have we any agent by which we can collect and press forward these scattered and lethargic drops of blood to the heart, and enable it to renew the circulation, and with it the blessings of oxygen to the body? My reply is emphatically—Yes! Flannel bandages from the toes to the trunk, around the abdomen, and from the fingers to the body, will effect this object perfectly. Remark that the effect is gradual, increasing with every turn of the roller, but would be in full force in about twenty minutes. By thus exposing the blood in the lungs to the action of oxygen in its diluted form, as it is in the air, instead of pure oxygen, the reaction would neither be too rapid nor too dangerous. In confirmation of my views, I have this day learnt that it is the custom in India to wear a double roll of flannel around the abdomen, as a preventive to cholera. The other advantages resulting from the use of the flannel bandages are:

1. That they prevent the escape of heat from the body of the poor creature who is already in a state of refrigeration.

2. By their firmly and equally grasping both flexor and extensor muscles alike, they are steadied, and rendered much less likely to be affected with spasmodic action or cramp.

3. By their steady *elastic* pressure and support of about 160 pounds, they persistently keep up and sustain the circulation of the blood, which they had previously restored.

4. That the oxygen thus well secured to the blood, will, I believe, prove quite sufficient to neutralize the original poison, and also destroy its effects.

5. That this much can at least be claimed for their use, that they remove from nature a stumbling-block, which prevented her from exercising her marvelous recuperative powers. Diluted sulphuric acid is the best medicine to arrest the flux from the bowels, acting also as a tonic. It should be given in five-minim doses about every half hour, with rice gruel. By adopting this plan, the natural process is brought about, that of the starch being converted into grape sugar. Plenty of white of egg, well whipped up, so as to nourish the body and convey oxygen into the stomach, which it will appropriate, should be given. Opium, in small quantities, and other stimulants, should be given according to the necessities of the case. May it not be well, through the medium of wet sponge over the thorax, to apply a continuous but gentle current of galvanism, so as to stimulate the heart's action, keep alive the respiratory movements, and thereby assist in the maintenance of the functions of the body?

New Mode of Localizing Bullets.

In the transactions of the Vt. Med. Soc., Dr. S. J. Allen, says:

"Perhaps I may be pardoned if I say, that dur-

ing the four years of the war I served in the field one year as Surgeon of a regiment, two years as Surgeon-in-Chief of a Division, and the last year as Medical Inspector of the Sixth Corps, and must have seen and examined, if not treated, many gun-shot wounds. In all I have examined, be they more or less in number, I never localized a dozen bullets with a probe.

"In nearly all not localized by the finger, or sense of touch, I succeeded in fixing with certainty their exact location by the use of the exploring needle.

"I claim that if the bullet did not enter either of the cavities of the body, but lays anywhere in the periphery among the muscles, or other tissues exterior to them, the exploring needle, in the hands of the surgeon, will, by puncturing a reasonable number of times, hit the ball, and convey the intelligence of its exact location.

"Had the exploring needle been used in the case of our late President, the 'encysted wad of puss in the right iliac region' would have been punctured without appreciable resistance, and his surgeon saved the Blissful diagnostic error contained in several of their bulletins, which located the fatal bullet at that exact point with absolute certainty.

"A serviceable instrument for this purpose will be found in the smallest sized exploring needle, with which, all will admit, it is quite safe and comparatively painless to make the puncture.

"It is not unusual to puncture not only the peritoneal cavity, the pleural cavity, and the bladder, but the intestines, and the pericardium, and seldom has harm resulted.

"The probe should be used only to determine the direction the ball took from its point of entrance, and to ascertain if it entered a cavity. Here, I claim, its usefulness ends, and if further used does harm.

"The surgeon almost always has an impression, after an examination, that the ball lies at a certain point. To test this impression, push the exploring needle from the surface directly down to this point. If it does not hit the resisting bullet, try at the next most likely point. If not successful, try again. The bullet can be localized in this way many times where all other methods fail. When the needle hits the ball, the surgeon will make the counter incision for its extraction with perfect confidence.

"Supposing that the bullet lies in close proximity to a bone, or is flattened upon a bone, by using a little more force, the point of the needle will be made to penetrate the ball slightly, and will stick a little, and thus convey to the surgeon's hand a sensible difference between bone and lead."

Etherization of the Rectum.

The *St. Louis Courier of Medicine*, May, 1884, says that Daniel Mollière, Surgeon-Major of the Hotel Dieu, of Lyons, France, communicates to the *Lyon Médical*, of March 30, some recent observations with reference to a novel method of administering ether, which would certainly have advantages in surgical operations about the face or mouth, even if not available as a general rule.

He states that a short time previous to the date of writing he had received a visit from a Danish surgeon, Dr. Axel Yversen, of Copenhagen. Having taken his visitor through the wards of the hospital, and shown him some of the most interesting cases, the latter asked what anæsthetic agent was used. On being informed that they used ether, he inquired whether they administered it by the mouth or the rectum; and went on to explain to Dr. Mollière his own obseevations.

On the following day, March 21, Dr. Mollière made a trial upon three patients of the new method of administering the anæsthetic. March 23, 24, and 25, other patients were anæsthetized in the same manner. In the first case a tube was passed into the rectum, through which the ether vapor was introduced by means of an atomizer. About twelve minutes elapsed before any sign of the absorption of the ether was manifested. The patient then said that she tasted ether distinctly, and her breath had a pronounced odor of ether. She then began to speak incoherently. A few drops of ether were then administered by inhalation, and she almost immediately fell into a profound sleep. The operation being terminated, the rectal canula was removed, and the patient speedily regained consciousness. The quantity of ether taken was insignificant.

In etherizing the other patients, an India-rubber tube of the size of the finger was introduced into the rectum, and connected with a flask of ether plunged into a vessel of water at about 50°C. (120°F.) The ether boiled, and in about five minutes the patient began to talk incoherently, and the odor of ether appeared in the breath. A small quantity of ether upon a sponge was then administered by inhalation, and very speedily the anæsthesia was complete. The operation was performed without difficulty. There was neither nausea nor the slightest vomiting.

He believes that this method of administering ether will prove to be a valuable one. So far as the cases upon which he had operated determine the effects of the agent employed in this way, it seems to suppress almost or entirely the period of excitation. It allows of accurate dosage of the quantity of ether administered, and reduces it to its smallest quantity. It does not interfere with the surgeon when making operations about the face.

Dr. Mollière promises to give further results and all details as to the *modus operandi* in a few months, when he shall have had further opportunities to test the method.

The Diagnosis of Acute Alcoholism.

From the *Brit. Med. Jour.*, July 12, 1884, we note the following:

Of the numerous cases brought to hospitals for advice and treatment, there are none, we believe, more difficult to decide on than those of persons found insensible in the streets. Very frequently they are cases of simple poisoning from excess of alcoholic drinks, especially of an adulterated and deleterious nature; but at times they are cases of disease, or are complicated by head-injuries, which, if not promptly recognized and treated, may ultimately prove of a serious nature. We are prompted to refer to the liability of errors of diagnosis in such cases, and the necessity for

great caution in dealing with them, by the recent occurrence in Glasgow of two cases of this nature, which have become public and have excited a good deal of comment in the public press. In the first instance, a young man is found insensible in the street, is taken by the police to the office, and is there seen by the medical officer in charge, who gives it as his opinion that the insensibility is due to alcohol. In the morning more serious symptoms show themselves, and medical treatment is resorted to, but unfortunately without avail. A post-mortem examination reveals that apoplexy was the cause of death. In the other case, a man is brought by the police to one of the infirmaries, is admitted there, and after a few hours is once more sent back to the police-office as suffering from excess of alcohol. Soon after his return to the police-station it is observed that his condition is not satisfactory; the police-surgeon is summoned, and his opinion is given that the man is suffering from some serious head-injury, and sends him back to the infirmary from which he had been dismissed only a few hours previously. Such incidents as these cause a painful impression on the public mind, and are calculated to destroy public confidence in the ability of professional men to recognize what is and what is not drunkenness, to say nothing of the serious consequences that must accrue to a patient suffering from some disease or injury of the brain, from being thus conveyed unnecessarily through the streets of the town at that early period of his illness when prompt medical treatment might prove of some avail. We can only say that such cases should serve as an instructive lesson to all those who are connected with the reception of patients at our infirmaries, and should impress on them the advisability of erring on the safe side, by not sending away any case about which there can be the shadow of doubt.

Pathognomonic Signs of Disease.

From the *Louisville Medical News*, we learn that Dr. E. G. Janeway, of New York, read a paper before the American Medical Association on "the danger of relying too much upon so-called pathognomonic signs of disease."

It is often a very brilliant thing, he said, to make a snap diagnosis, but it is not safe to do so; for many so-called pathognomonic signs of special diseases are found, on closer inspection, not to be so in reality. For instance, optic neuritis, conjoined with headache, used to be considered as a pathognomonic sign of cerebral tumor. This is not so. We know that it only means that there is some increased pressure in the brain. You must also eliminate Bright's disease of the kidneys. Volitional tremor is thought by some to be very characteristic of multiple sclerosis, but a similar condition is observed in patients who are under the influence of metallic poisons, such as mercury, and also in those who have partaken freely of alcoholic stimulants. We often find considerable difficulty in cases of coma, in endeavoring to decide whether it is of hemorrhagic or uræmic origin. The variations in the temperature of the body are here a valuable help in our investigation; but they are not sufficiently certain to found a positive conclusion upon. The existence of heart-murmur, or the absence of it, does not positively settle the point as to whether there is an embolus in the brain or a hemorrhage; and albumen in the urine is often associated with these lesions. The author went on to consider cases—referring to heart and chest diseases. It is not wise to rely too much upon these signs, but to take the whole bearing of the case in making the diagnosis.

Dr. Frank Donaldson, of Baltimore, in opening the discussion, spoke of cardiac murmurs. He had known of cases in which the autopsy showed marked stenosis of the mitral orifice, which has presented no murmur during life.

Dr, Janeway said that in some cases of pleurisy of slight grade, bronchial breathing is not present, and he has seen people much misled by it. In regard to mitral stenosis, he thought that it could sometimes be detected by a long first sound with a slightly blubbering character, even when there was no murmur.

The Chemistry of Wines.

The *Pharmaceutical Record*, February 1, 1884, tells us that the chemical examination of wines is treated exhaustively in a paper by Dr. L. Roesler, published in first *Heft* of the *Mittheilungen der k. k. chemisch-phisiologischen Vereinsstation für Weinund Ostbau in Klosternenburg bei Wein*. Very full details are given of the methods for estimating in wines the specific gravity, the alcohol, extracts, free acid, tartaric acid, tannic acid, acetic acid, sugar, glycerine, nitrogenous matters, ashes, and the various dye-stuffs used in sophistication.

The methods of determining alcohol are also detailed in a separate paper, following the foregoing, prepared by Dr. B. Haas. Ordinary red wine made by fermentation of grape juice, is a very complex liquid; the following list of substances contained in it is far from being complete:

A. Products of Fermentation.

Ethel	alcohols	Acetic	ethers
Propyl		Caprylic	
Butyl		Capric	
Amyl		Glycerine	
Hexyl		Fatty matter	
Heptyl		Succinic acid	
Aldehyde		Gummy matter	
Acetic	acids	Carbonic acid	
Butyric			
Caprylic			
Capric			

B. Products of the Grapes.

Water		Pectin	
Dextrose	sugars	Albuminoids	
Levulose		Œnocyanin	
Inosit		Argol	
Tartaric	acids	Tartrates of	calcium
Racemic			alumina
Malic			iron
Tannic			
Fatty oils		Phosphates	potassium
Ethereal oils		Sulphates	sodium
Gums		Chlorides	calcium
			maguesium

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE INTERNATIONAL HEALTH EXHIBITION.

Our readers are aware that during the past spring there was opened in London, under the auspices of the Prince of Wales and many of the nobility of England, an International Health Exhibition, on a very extensive scale. At the time we were gratified, because the fact that such an exhibition was contemplated, and had been carried to a successful opening, was evidence that people were developing an interest in preventive science. All the important European countries were represented. Food, clothing, drainage, water supply, and all pertaining to sanitation, were fully illustrated in this remarkable collection. Pasteur sent from France specimens illustrating his researches on micro-organisms, as well as a corps of assistants to explain his methods and results. A very interesting feature was a model of a street in London, as it appeared two hundred years ago; by a comparison with which, those of the present day and generation are enabled to note the improvements (from a sanitary point of view) which have taken place in the methods of collective life of human beings. During the course of the exhibition, a series of lectures on sanitary topics has been delivered by some of the most eminent physicians and sanitarians of London, while health tracts have been widely distributed. The exhibition itself, as well as the lectures and tracts, have all been designed and prepared with the view rather of instructing the public in matters pertaining to hygiene. How well it has succeeded may be inferred from the fact that during the first month that the exhibition was open, it was visited by more than 500,000 persons. It is also stated that it has proved so attractive and has drawn away from the theatres so many of their patrons that the theatrical managers are seriously contemplating the idea of presenting a petition to the Prince of Wales, requesting him to withhold his patronage from these exhibitions. We are glad to be able to report the phenomenal success of this exhibition, as it shows very plainly that the people are waking up to the great value of preventive science. If properly understood, a popular knowledge of hygiene would not redound

to the pecuniary disadvantage of the physician; that is, not to the detriment of the mass of the profession; because, no matter how familiar a person may be with the teachings of hygiene, when really sick he will send for a doctor, and even now the mass of the people *doctor* themselves unless they are really very sick. Of course the fashionable physician, who is called for trifles, might possibly suffer a little, though we doubt even this; but we are very sure that the mass of the profession would not lose one cent. Let us then do our noble duty, by instructing our patients in the valuable precepts of hygiene.

The success of this exhibition tells us in no uncertain terms that the public desire this instruction, they hunger and thirst for it, they are ready to do right, if told how to do so, they want to know how to preserve health and attain longevity. Let us help them, let us supplement the noble and self-sacrificing work of our lives by imparting to them this all-valuable knowledge.

SCIENTIFIC VS. PRACTICAL MEDICINE.

Said a prominent physician recently, "I am tired of reading about scientific medical discoveries; what I want, is to know how to cure consumption, cholera, and so on."

This sentiment is, no doubt, shared in by very many of the profession. For some years past, we have been hearing an immense amount about germs, bacilli, micrococci, and the like, but we venture to say that as yet this scientific investigation has produced very few practical results. We do not mean to belittle the scientific side of our profession—far from it; but we do incline to think that the greatest practical results have been achieved, so to speak, by accident. That is to say, that when a man starts out with a theory which he endeavors to demonstrate through scientific methods, he is very apt to view his results through biased glasses, as it were, and in the majority of instances he will find sufficient evidence to prove that which he desires to prove, and which, according to his preconceived theory, *ought* to be the case.

On the other hand, when an acute observer carefully notes his cases at the bedside, he is now and then struck with some unusual feature, which may probably, and often does, suggest to his mind some theory, which, retained in his memory, is either proved or disproved by further clinical observation. The facts here suggest the theory, while with the scientific observer the theory suggests the facts.

Jenner's discovery of vaccination was suggested by a fact. It is well known that hearing a dairymaid remark that she could not take small-pox because she had had cow-pox, Jenner's ready mind was impressed by the remark, and having ascertained it to be a fact that those who had had cow-pox were remarkably exempt from small-pox, he started to reason and investigate from the premises of facts, with the result of giving vaccination to the world. This wonderful discovery was not the outcome of a previously formed theory, but the logical and rational conclusion of a well-ascertained and recognized fact.

So has it been with all great discoveries in medicine. The laws of nature can be so twisted and turned in their interpretation by a prejudiced mind that is not a very difficult matter to find seemingly convincing arguments of almost any theory that suggests itself to the mind of man.

We have penned these few words to warn our readers against being carried away by the beautiful and attractive theories that are now being advanced in the medical press. As matters of speculation they are all very nice, but as a means of enabling us to further extend the mission of our profession, to cure disease and relieve human suffering, they have not been demonstrated, as yet, to be of any value.

LABEL POISONOUS PRESCRIPTIONS.

This warning is suggested by a most lamentable occurrence that took place recently in this city.

A physician prescribed some pills containing strychnia, with the directions that one should be taken before each meal. The prescription was filled at a most responsible drug store.

The label on the box contained the directions for use and the doctor's name.

Several friends of the person for whom the strychnia was ordered were assembled together, when one commenced to banter the other, and they dared each other to eat a lot of the pills. The challenge was accepted, with the result that there was one death in a few hours, and three or four very sick people, whose lives were saved only by the most prompt and energetic measures.

The remark has been made, in connection with this case, that persons who are fools enough to eat a lot of pills deserve to be killed.

This, however, is clearly an erroneous view to take of the matter. It is a common practice among druggists to dispense poisonous liquids in blue bottles, and to paste the word Poison in large letters in a conspicuous place. Would it not be well to establish the same rule with reference to poisonous pills and powders? It is hardly likely that any amount of bantering would induce even the most ignorant person to swallow an indefinite and unprescribed quantity of any pills or powders, while the word POISON and the characteristic and suggestive skull and cross-bones were staring them in the face.

A SIMPLE REMEDY IN DIARRHŒA.

In the late summer and autumn, when fruit is so abundant, any simple remedy for diarrhœa, and what is familiarly called "bowel complaint," is worth knowing and remembering. Such a one was recommended by Dr. T. E. STELLWAGEN several years ago in his edition of Coleman's "Dental Surgery," and more recently in the pages of one of the journals. It is simply *vinegar*, preferably sound cider vinegar. The dose is about two ounces for an adult, and should be swallowed "neat"—without admixture of water.

It may also be given to infants with excellent results. To a babe a year old a teaspoonful of moderately-diluted vinegar would be the proper dose.

Its effect is to check pain, tenesmus, and tormina at once, to relieve the chill and cramps when present, and to disseminate a feeling of warmth and comfort over the body.

Even in cases of chronic diarrhœa which have long resorted treatment, this household remedy has succeeded in checking the discharges and correcting the sub-inflammatory condition of the membranes.

We shall be glad to report any experiences, favorable or otherwise, which our readers may have with this remedy.

NOTES AND COMMENTS.

A Highly Interesting Record.

In a village, C., near Weimar, where for many years no case of tubercular phthisis had taken place, two years ago several families suddenly discovered one of their members to be suffering from the disease. After a long inquiry, it was discovered by accident that all these families had been buying their spring chickens from one and the same place, viz., from a private hospital in the neighborhood. A medical student brought the livers of two such chickens to Prof. Johne, in Dresden. The student, whose own sister had become affected with consumption, had lived during his vacation at home with his parents, in C., and he had there at dinner observed the peculiar appearance of the liver of the chickens.

On examination, both organs were found to be full of tubercular bacilli. A thorough investigation was at once instituted, and it was then that the fact came to light that the chickens eaten by the families, members of which had been infected with tuberculosis, had all been bought from the institution mentioned. On further inquiry at the latter place the following facts were elicited:

At about the time when the first case of consumption occurred in the village, an inmate of the hospital, Mrs. R., had died of the disease. Before her death, Mrs. R. used to feed the chickens raised there; she was often seen first to chew the meat before she gave it to the chickens. Further, the spittoons were emptied on a place in the yard where the chickens generally came to pick up any stray corn.

As none of the chickens ever came in contact with any animals in the neighborhood—the hospital being situated at a considerable distance from the village—as no disease had happened amongst them until the arrival of Mrs. R., when soon after an epidemic seemed to break out

amongst them, and many died—there is no doubt that they contracted the disease from Mrs. R., and in return infected those who ate their flesh.

The case is very interesting, first, as it proves how such animals may become affected, then how they may spread the disease, and lastly, that some kind of a disposition must exist in the person infected; for here, of many who had eaten of the diseased flesh, only a few contracted the malady. The whole report teaches us how careful we have to be, and how necessary is the appointment of skillful experts by the State to inspect all food offered for sale.

Constipation.

The *New Orleans Med. and Surg. Jour.* says that an article on constipation in *Squibb's Ephemeris* for May, may be thus summed up: Constipation is an undue accumulation in the intestinal canal of excrementitious matter which should be discharged at least once daily. The immediate cause of the kind of constipation under consideration is the dryness and hardness of the residuary matter, which has resulted from over-absorption of the moisture contained in this matter before it reached the large intestine. The average ingesta of a healthy man is five pounds two ounces, of which 79 per cent. is water. The average residue is 5.25 ounces, of which 75 per cent. is water. The object in any course of treatment, then, is to keep these proportions constant. If the percentage of water in the excreta is below 50 per cent. the intestines can propel it with difficulty, and if below 20 per cent. they can hardly move it at all—the result is obstinate constipation.

The blood naturally is 79 per cent. water, and this water is the solvent and is for both supply and waste. If too much water is secreted by the various surfaces, or not enough is taken with food, then the blood takes it from any source possible, and the most natural source is the alimentary canal. Therefore water must be taken in sufficient quantity, alone or with the food, or in the shape of succulent food, especially fruit. It is stated that after the first stages of digestion—one to two hours after a meal—there is a special call or appetite for water, which should be gratified. Again, exercise often relieves constipation by creating a desire for large amounts of water. Too much clothing by increasing perspiration, depletes the blood, which supplies the deficiency from the intestines.

The whole treatment summed up is: Take enough water with food and a large glass in the later stages of digestion. Watch for and satisfy an appetite for drink between meals. This should be persisted in for a few weeks. If it fails, add laxative elements to the food, such as fruit, along with exercise. It may be necessary to use some aperient, but only in small doses and largely diluted, and at bedtime or one hour before breakfast.

Inspissated bile may result from deficiency of fluids. Increased fluids may cure this and the resulting constipation. If not, then a drug which acts especially upon the duodenum, *e. g.*, calomel or some combination of taraxacum or podophyllum, taken preferably at bedtime for a day or two, will often relieve this condition, which can be prevented from recurring by the proper use of liquids.

Large Doses of Sulphate of Copper in the Vertigo of Meniere's Disease.

M. Charcot, at a recent clinic at *La Salpetrière* (*Gazette des Hopitaux*), presented two cases of vertigo, with the characteristic shrill sounds, intense hissings in the ears, followed by the sensations of movement in various directions.

The first patient presented these symptoms to a very marked degree on entering the hospital; he had been under the treatment since that time, for a space of three and a half months. First the vertginous symptoms disappeared, until now there only remains the staggering on walking, or the cerebellar vertigo, which is much more difficult to overcome than cerebral vertigo. He was treated as follows: For twenty days he was given daily twelve (12) grains of sulphate of quinia. Then a suspension for ten days. For twenty-seven days the same dose, followed by a suspension of eight days. For twenty-two days the same dose, suspension for nine days. For nineteen days to date of observation the same dose.

The second case was completely relieved. This patient was a woman who was obliged to keep her bed for seven or eight years on account of the severity of these symptoms. She has been for a number of years under this same course of treatment. In 1875 she already showed marked signs of improvement—no longer having habitual vertigo, nor exacerbations, nor disordered movements, nor those sensations of falling which kept her to her bed for so long a period; but at that time she still walked with difficulty, with hesitation, and staggering like a drunken person—or like one having been deprived of the use of the legs for a number of years. Now she presents the ap-

pearance of one completely cured, walking without the slightest hesitation and with a firm step. Her health is perfect.

Resection of Muscles in Infantile Paralysis.

The *Brit. Med. Jour.*, May 31, 1884, says that Mr. Keetley has recently undertaken the resection of part of the quadriceps extensor femoris in a case of infantile paralysis, causing inability to extend the right knee. By shortening the weak, relaxed, and partly atrophied muscle, the operator hoped to increase its strength, with the aid of electricity during recovery from the operation. Mr. Willett has already resected the tendo Achillis in paralytic talipes calcaneus, with good results, finding that the shortening of the abnormally elongated tendon enables the muscles of the calf to regain some portion of their lost functions, especially when the muscular wasting has been chiefly due to disease, and has not advanced too far. Mr. Keetley's patient was a boy aged 6, who had suffered from paralysis of the right lower extremity for four years, and the muscular atrophy was not complete, yet sufficient to prevent thorough extension of the knee. A longitudinal incision was made in front of the thigh, about three inches in length, ending an inch above the patella; the skin was held apart by retractors, and one inch of the entire substance of the quadriceps was cut away with scissors, about two inches above the patella. The separated ends were united by means of about one dozen carbolized catgut ligatures. Esmarch's bandage had been applied before operation, and only one small artery required ligature. The wound was dressed with a small iodoform pad and carbolic gauze, and the limb placed on a back-splint, at an angle of sixty degrees with the bed. The operation was performed on May 5th. The wound healed rapidly and perfectly; and when a sufficient time has elapsed, the results will be made known.

Electric Treatment of Strangulated Hernia.

They seem to have in Russia a great deal of confidence in the electrical treatment of strangulated hernia. The *Allg. Med. Centr. Zeit.* of June 7th, 1884, brings the following three reports from the Russian Medical Journal *Wratsch* (transl. *The Physician*):

Dr. W. Woloshkewitschszk had a patient, in whom an inguinal hernia of ten years' duration had become strangulated. Baths, attempts at taxis, sprinkling of ether over the swelling, all were in vain. Then faradization; after five minutes' application the tumor became smaller, and finally total disappearance of the swelling, with a gurgling noise.

Dr. Lew reports an inguinal hernia of twenty years' duration, strangulated for fourteen hours. In this case, too, after all the usual means had given no result, the application of faradic electricity for ten minutes enabled the operator easily to perform taxis. One pole was applied to the swelling, the other to the ring and the neighboring abdominal walls.

Another case, where the strangulation had lasted eight hours, had an equally favorable result, the tumor disappearing after faradization of fifteen minutes. The operation in the last case was by Dr. Kobktsccihewrsky.

Painless Death for Animals.

At the annual meeting of the Royal Society for the Prevention of Cruelty to Animals, held in London on July 7, Dr. B. W. Richardson described a method recently adopted at his suggestion for destroying lost and starving dogs by a painless death. This consists in submitting the animals to the influence of carbonic oxide gas in a closed chamber, the carbonic oxide being charged also with chloroform by being made to pass over a porous surface saturated with that drug. The result is that the animals to be killed fall at once into a deep painless sleep, out of which they never recover. Dr. Richardson has, for a long time past, been engaged in experimenting with a view to determining the best mode of killing animals without the infliction of pain, and the apparatus he describes is the fruit of his researches. He is sanguine that by-and-by the humane system of slaughtering will be applied even to the destruction of animals intended for food; and he has himself applied the method with complete success in the case of sheep, which are first driven into sleep, and, while thus unconscious, killed. The good wishes of every humanitarian will be with Dr. Richardson in this.

Internal Use of Nitrite of Amyl.

In the *Brit. Med. Jour.*, July 19, 1884, Dr. J. F. Dixon calls attention to the fact that there is only slight mention in the text-books, and scarcely any reference in periodical literature, to the internal use of nitrite of amyl. Its very temporary and ephemeral action, when inhaled, has plainly caused therapeutists to cast about for an agent

which produces more continuous results. He believes that, in nitrite of amyl given internally, we have a drug which meets all the requirements of cases in which it is important to lower the arterial tension, and further, that it is free from the uncertainty of action, and the sometimes dangerous results of nitro-glycerine and nitrite of sodium, which have been employed apparently as substitutes for it. He has employed it thus in cases of anginous attacks of a very severe character. One, complicated with very loud mitral systolic murmur and nightly angina; the second with an aortic systolic murmur; and the third with irritable action, but no apparent organic lesion. The dose was 2½ minims three times in twenty-four hours; of course, seeing the case twice daily until the action of the drug was established, when a dose each night was sufficient.

Numbness of the Hands.

A correspondent having requested some information on the subject, Dr. E. Downes writes to the *Brit. Med. Jour.*, July 12, 1884, that he thinks that there is a good deal of evidence to show that it is a symptom of gout; probably there is some gouty infiltration in the the sheath of the nerves, or possibly in the sheaths of only such nerves as are predisposed by being subjected to pressure, such as the ulnar, when a person lies on his side for some time.

In any case, an alkaline treatment, with perhaps iodide of potassium, is the best to adopt. After the symptom has existed for some time, only on waking, there is undoubtedly a tendency for it to remain present more or less permanently; in such cases, blistering is needed, and will do much good. But he is sure that one great point is to prevent pressure on the ulnar nerve. This may be done in many ways, but none is better than a very simple expedient, namely, to rest the arm, just above the elbow, on a rather soft book, like a "Bradshaw," but not the thickness of the full edition of that book. This takes all the weight off the elbow, and causes no discomfort. Feather beds and spring mattresses are both to be avoided; a good hair mattress is the best.

A New Antipyretic Method.

Dr. Preyer (*Centrlb. f. d. Med. Wiss.*, 23, 414), discovered, that the temperature in the rectum shows a decrease of from 3° to 7° C. in guinea-pigs, upon whose cutaneous surface a spray of lukewarm water has been playing for twenty minutes. It is possible that the fine spray of the atomizer, moistening the hair of the guinea-pig, causes such a rapid evaporation that the temperature declines. Whether the same would happen

[redacted]

lukewarm water, as practiced in the form of spray by Preyer on guinea-pigs, be followed by the same good result in human beings, the new method would be a decided gain.

Veratria in the Pruritus of Women.

The *Med. Times and Gaz.*, April 12, 1884, says:

All acquainted with the incessant suffering which some women undergo from pruritus at the period of the menopause, must be very desirous of being made acquainted with a prompt remedy for so distressing an affection. Whether it arise from the presence of prurigo, urticaria, eczema, herpes, or whether it exist without any eruption at all, it is alike difficult to allay, as the great number of remedies which have been proposed testifies. Of these veratria is by far the most efficacious. When the pruritus is localized at the groins, arm-pits, walls of the abdomen, or behind the ears, gentle friction night and morning with an ointment consisting of thirty parts of lard and a quarter of a part of veratria, usually gives relief. When the pruritus is generalized, the internal administration of the veratria is preferable. Two centigrammes should be made into ten pills, with licorice powder, of which from two to six should be taken daily, either half an hour before or three hours after meals. Only one should be taken at a time, an additional one being given each successive day until the maximum of six is attained.

New Cure for Lupus.

The methods hitherto employed for the radical cure of lupus consisted either in its removal by the knife or in its cauterization, thus causing its destruction. But its extirpation with the bistoury has great dangers, as erysipelas frequently

develops itself. Caustics also have their disadvantages; they cause a great deal of pain. The cure is a very slow one, and disfiguring cicatrices follow their application.

Resorcin as an Anodyne.

When exposing the integument of frogs for a longer time to the influence of resorcin, Dr. Andeer (*Aerzt. Intlgbl.* 10, 1884,) noted a remarkable insensibility of the animal to all external, no matter how painful impressions.

This observation induced him to make a trial in the human being. The result was so satisfactory that he does not hesitate to recommend the drug in all diseases of the mucous membrane associated with pain. So in chronic affections of the larynx, of the intestinal canal, the genital organs, and of the heart, and in colicky complaints of whatever nature, the remedy acted with the greatest promptness in subduing pain. He himself suffered from a painful trouble of the stomach and intestines as a sequela to typhoid. The complaint did not yield to any drug; the pains always returned until he employed resorcin, which put a sudden stop to them. The dose of resorcin varied from 16 to 160 grains, or if administered in the form of clysmata, a $\frac{1}{50}$ solution is to be recommended.

The Treatment of Abscesses from Congestion.

M. Verneuil (*Semaine Médicale,*) has treated abscesses from congestion or ossifluent abscesses, by a new method, which has been followed by very good results. The sac of the abscess is emptied by means of an aspirator. A solution of 100 grammes of sulphuric ether and five grammes of iodoform is then injected into it until the cavity is full. If, after a few days, abnormal fluid reappears in the sac, the operation is repeated. M. Verneuil has never injected more than twenty grammes of the solution. A larger dose produces toxic symptoms. A certain proportion of ether passes into vapor, and the sac becomes inflated, but this subsides very quickly from absorption. After each injection less and less pus appears in the sac. The general condition also improves. After emptying the sac, many surgeons, among others Dr. Lannelongue, have recommended scraping the walls and cauterizing with a solution of carbolic acid.

Three Cases of Lacerated Perineum Treated by a Single Suture.

Dr. H. J. Lee, of Cleveland, Ohio, reports three cases in the *American Journal of Obstetrics* for July, 1884, wherein he obtained most excellent results from the use of a single suture.

A silver-wire suture was introduced *on a level* with the *commencement of the laceration;* it was carried to the very bottom of the wound, and out upon the opposite side, including fully a half an inch of tissue on each side of the tear. The ends of the wire were twisted together, and the patient made comfortable in bed. The sister in charge was directed to give carbolized injections, and told to use her eyes in introducing the vaginal tube, and be careful to pass it above the suture. This she was very careful to do, and the wound united very nicely, and the suture was removed on the tenth day. There was not an untoward symptom during the whole progress of the cases.

The single suture will probably not answer when the sphincter has been torn through.

Glycerized Iodine as an External Application in Small-Pox.

The *London Med. Times* informs us that Dr. Bartholou, an army-surgeon, relates in the *Lyon Médical,* February 3d, some additional cases, in order to show the great advantage which may be derived in very bad cases of small-pox, by painting the surface with the following mixture: tincture of iodine, 30 parts; glycerine, 60 parts; and iodide of potassium, $\frac{1}{4}$ part. The application is not unpleasant to the patient, and may be made from the fifth or sixth day of the eruption to the eleventh or twelfth. During this period, it is repeated four times daily, and powerfully contributes to the absorption of pus, and the desiccation of the pustules, after which it is discontinued.

Pepsin in Diabetes.

When a diabetic patient, under the diet which deprives his system as much as possible of the introduction of more hydrocarbons, seems to lose in

weight, while the diabetic symptoms still continue, or if a diabetic patient greatly suffers from indigestion, or if an examination shows that most of the food, which he takes passes off undigested, the regular administration of pepsine and of peptones is followed by good results. The patient need then not be limited in his diet, but he will decidedly improve in general health, and the quantity of sugar in the urine will lesson. Dr. Giovanni (*Allg. Deutsch. Med. Z.*, 40, 1884), treated a number of patients on this plan with such an excellent effect, that he is of the opinion, that the treatment proposed will at least prolong life, preserve the strength, and maintain the general health of a diabetic patient.

The Treatment of Cholera.

CORRESPONDENCE.

The Limitation of Families.

EDS. MED. AND SURGICAL REPORTER:

I quote from REPORTER of July 26th, the following from a lecture delivered by a distingushed professor of your city: "Let me take this opportunity to adjure you as physicians to resolutely set your faces against the practice of preventing conception. * * * * When wives voluntarily degrade themselves to the position of the mistress, when they defile the marriage bed with the appliances of the brothel, what wonder is it that they find the honor of their husbands weakened, and the loyalty due them lost in selfish indulgence not more criminal than their own."

I have noted from time to time that Professor Goodell, in his clinical lectures, voices with much emphasis similar sentiments, but goes much further in depicting the penalties of such practices, by describing the dire physical as well as moral evils which result therefrom (notwithstanding the fact that most of his operations are to repair the accidents of childbirth).

He even devotes a whole chapter of his most excellent book on "Diseases of Women" (if my memory serves me rightly), to presenting a powerful plea against any effort being made to control the number of offspring in the family.

Now, with all due deference to the opinions of these eminent physicians and teachers, I ask, isn't there a good deal of cant and humbug displayed in such statements?

Something depends, of course, upon just what privileges the gentlemen grant to the married state. From the tenor of Prof. Waugh's opinions, we must infer that he would limit sexual commerce to the single object of perpetuating the race. Any less rigid rule would tend to pleasure merely, and that would again suggest the dreadful analogy he draws between wife and mistress. He intimates in his remarks that ladies of high degree, socially and religiously, are familiar with the appliances of the brothel—though what is meant here can only be conjectured, for it is generally understood that barrenness among the dissolute is the result, not of special practices, but from over-excitation of the generative organs, which in such a condition antagonizes conception.

But grant, if you please, that reputable women *have* adopted, for self-protection, the "methods of the brothel." Such a concession affords, to my mind, evidence exactly opposed to his argument; for therein lies the greater shame and reproach to the family physician and adviser who, from false delicacy, neglects to instruct his gentle patients how to protect themselves without physical injury, and also without sacrificing anything of modesty or morality.

I think that no one will deny, in these days of sharp competition and rapid increase of population, the propriety of limiting the family to that number only that can be comfortably provided for and educated. Anything beyond this limit results in poverty to the individual, and increases pauperism and crime in the state. Hence, some check must be provided, is the conclusion that sensible thinking people have arrived at, and a knowledge of which they are now demanding of their medical advisers. We must respond to this demand, and in such a way as to serve the cause of good morals by sensible outspoken advice, or worse will come of it. And to say that such knowledge will be put to improper use now and then, is only begging the question and shirking responsibility.

Once this knowledge becomes general, and *criminal abortion*—the crying evil of the day—will be relegated to the past.

In Utopia, or during the millennium, or some other equally distant place or time, the professor's degree of continence may be practiced; but so long as the present conditions of society exist, and the human heart continues to respond to the influences of feeling and passion, it becomes us to look upon men and women as they *are*, and not as impracticable theorists and cold-blooded

dreamers have asserted they *ought to be;* and, so far as we possibly can, endeavor to guide them into straighter paths, illumined by clearer and purer lights. DAVID E. MATTESON, M. D.
Warsaw, N. Y.

Removal of Foreign Body from Ear: Fifteen Years' Loss of Hearing Restored.

EDS. MED. AND SURG. REPORTER:—

I was called on June 15, 1884, to see a young man (a miller by trade) who was suffering from a severe attack of cholera morbus. During my visit the patient stated that he wanted me to examine his ear—that there was something in it that caused almost total deafness. Not having my ear speculum, syringe, or any other instrument at hand that would probably be necessary for its removal, I advised him to come to my office as soon as he could travel, and I would explore the organ carefully, and extract the offending object, whatever it might be, if possible.

June 21 the young man called at my office. Upon illuminating the external meatus, after dilating well with the ordinary bivalve ear speculum, I discovered that its bottom was filled up to the depth of one-fourth inch with a rough, hard, ragged mass, almost hidden from view by pus, which was being excreted freely. To remove the pus; I loaded a long, slender dressing forceps with fine cotton wool, brushed the pus from the foreign body, disclosing its true character, which was that of a wad of lint. Knowing that the mass was too firmly imbedded in the external meatus to remove with a syringe-spray of water in the usual way, I introduced the hook end of the Gross ear probe between the wall of the meatus and the foreign body. After getting the instrument in, I rotated the hook into the mass of lint. I now used a little traction, which brought the foreign body out, leaving nothing behind. After I had the pus well washed out of the ear, the patient stated that he could hear now for the first time in fifteen years. In the centre of this wad of cotton, which was the size of an ordinary pea, was a grain of wheat in a modified hard state.

The history of the case is that fifteen years ago, while working at his trade, he discovered that there was something in his ear. Failing to get it out, he dropped a small quantity of Harlem oil into it, which was followed with apparent relief of all difficulty, except the deafness, which from first to last grew worse rather than better. I prescribed equal parts of olive oil and glycerine with carbolized water as a wash, which the patient used for six to ten days with complete restoration of hearing power. J. U. BLOSE, M. D.
Cherry Tree, Pa.

NEWS AND MISCELLANY.

Death through Falling on a Slate Pencil.

An interesting case, unfortunately attended with a fatal result, is reported in the *Medical Press*, the victim being a little girl three years of age. While on the way to school, accompanied by an elder child, the deceased tripped and fell, and in doing so struck the angle of the right eye with the sharp point of a piece of slate pencil held in one hand. A slight amount of hemorrhage ensued; but after the shock of the accident the child seemed none the worse for some time. In about three weeks, however, she complained of pain in the eye and head, and symptoms of acute inflammation rapidly supervened; convulsions set in, and in little more than twenty-four hours the little sufferer was dead. The medical evidence at the inquest attributed the result to meningitis induced as a consequence of the injury to the eye, the wound inflicted on which had, however, entirely healed; and the case possesses many features of interest in this connection. At present no details have been given respecting the constitution of the patient, except that she is described as having been a "very healthy child;" but the occurrence of such cases has been sufficiently often recorded to make it not improbable that a correct explanation has been given in this instance.

The Detection of Adulterations in Paris.

The great services rendered by the Municipal Analytic Laboratory, recently established in Paris, are clearly shown by the criminal returns just published. Naturally, adulteration is more extensively practiced in the great metropolis than in the country, and a large proportion of the articles adulterated in the provinces are brought to Paris to be sold, either for local consumption or for foreign exportation. The disclosures made at the Municipal Laboratory, however, enabled the authorities to obtain 1134 convictions in 1880, 784

in 1881, and 637 in 1882; and this is equivalent to a reduction of 44 per cent. in three years. Of course, this fact does not warrant the assumption that adulteration is less prevalent in exact proportion with these encouraging figures. Something may be said for the increased skill of those who seek to avoid detection, and perhaps also the investigations have not been conducted with the same energy as formerly. New brooms proverbially sweep clean; nevertheless, even if we allow a liberal discount for all these considerations, there still remains a broad margin which we may consider as the demarcation of a solid improvement.

A British Cholera Commission.

The announcement is made that the British Government have appointed a cholera commission consisting of Dr. Klein, F. R. S., and Dr. Heneage Gibbes, who have been directed to proceed forthwith to India to pursue a scientific inquiry into the nature of cholera. It is understood that these gentlemen will act in conjunction with the commission nominated a few weeks ago by the Indian Government for the same object. "In the prosecution of their labors," remarks the *Lancet*, "Drs. Klein and Gibbes may be assured of the hearty good wishes of all Englishmen, and the results of their mission will be awaited with great interest. The government, in arriving at this decision, have only done that which ought to have been done twelve months ago; and it cannot fail to touch the national pride, that the country which has the largest interest in ariving at a sound conclusion upon the nature of this disease, should have allowed Germany and France to have preceded it in the research. It is better, however, to be late in the field, than to ignore the value of such an inquiry altogether."

Hoboken's Water Supply.

A public meeting was held in Hoboken on the 27th of July, for the purpose of taking some action in securing a better and purer supply of drinking water, which for the past ten years has been obtained from the Hackensack river. Prof. Leeds, of the Stevens Institute, who had been employed by the mayor to make an analysis of the water, stated that he had found in it large quantities of vegetable matter, which, while it might not be injurious to health, rendered it objectionable. This accumulation of vegetable matter, he thought, was due to the recent heavy rains, and he expressed the opinion that the evil would not be abated until the reservoir was thoroughly cleaned. This one of the engineers in the employ of the water company promised would be done, and the meeting adjourned without taking definite action in regard to the matter.

Vital Statistics from St. Petersburg.

From a consular report recently published, it seems that at the examination of recruits for the Russian army during 1882, of 1000 candidates examined, 460 were rejected as being "too narrow chested," 50 had pulmonary tuberculosis, and 10 "poverty of blood." On the whole 57.5 per cent. were rejected for physical disability. It was found that over 50 per cent. of the young men of St. Petersburg, between twenty and twenty-two years of age, were "weak and sickly." Of the population of the city, 2000 were affected with bodily infirmities; 771 were blind; 707 deaf or dumb, or both: 188 without arms; and 282 without legs. Blindness was twice as common among women as men, but the latter show a large proportion of cripples. Of the 771 blind, 134, and of the 707 deaf and dumb, 409, cases were congenital.

Cholera and the Migration of Birds.

The *Med. Record* tells us that the fact that the swallows, which migrated from Marseilles at the outbreak of the pestilence, have not yet returned, and that there are no sparrows at all in the city, is adduced as evidence that the atmosphere is still vitiated. This migration of the birds has made a deep impression upon the public mind, and has led to a demand for a purification of the atmosphere by means of bonfires.

Therapeutic Preparation—Infant Food.

The prepared food for infants or invalids known as "Mellin's Food," contains no starch or cane sugar, and is of a moderately alkaline reaction, thus avoiding many objections to which such foods are often open. From what we are informed of its action, it is well-suited to both classes for whom it is designed.

Items.

—The death of the distinguished ophthalmic surgeon, Professor Jager, is announced from Vienna.

—In the *Lancet*, July 12, Dr. Dobie reports a case of abscess of kidney with aspiration of forty-two ounces of pus, and complete recovery.

—The reports from the Greely Arctic expedition show that Americans can live for two years in perfect health in the Arctic region, and that the use of brackish water does not produce scurvy.

—The "Progrès Médical" learns that Prince Ludwig Ferdinand, of Bavaria, wrote his inaugural thesis on the anatomy of the tongue, "A Study in Comparative Anatomy." There were fourteen sheets of text and one hundred and four chromo-lithographs.

—A case of nicotine-poisoning is reported from Marienburg. The victim was a schoolmaster attached to the gymnasium there; he had long been in the habit of smoking extremely strong cigars, which gradually upset his nervous system, and he at length succumbed to nicotine-poisoning.

—We find in the Lisbon *Correio Medico* the results of numerous experiments made by Dr. Biondi on sheep, dogs, and cats. Partial extirpations, and amongst others that of both apices, were all followed by cure, while total extirpation of one lung was successful in about 50 per cent. of the cases.

—Dr. John Bassett Chapin, Superintendent of the Willard Asylum for the Insane, at Willard, N. Y., has been unanimously elected by the Board

of Managers of the Pennsylvania Hospital for the Insane to succeed Dr. Thomas S. Kirkbride, deceased, as Physician-in-Chief and Superintendent of that institution.

—Dr. Eugéne Ritter, Professor of Medical Chemistry and Toxicology at the Faculty of Nancy, has died, aged 47. M. Ritter was chosen six years ago, in consequence of his well-known scientific attainments, as one of the judges in a competitive examination of the professeurs agrégés, at the Paris Medical Faculty.

—The Imperial Carolinische-Leopoldinische Academie of German Natural Philosophers has awarded its highest distinction, the gold Cothenius medal for 1884, to Dr. R. Heidenhain, of Breslau, for his "studies connected with gland-secretions and the physiology of muscles, which are of lasting value to physiology."

—The following is Yvon's paraldehyde elixir for insomnia:

℞.	Paraldehyde.	10	grammes.
	Alcohol at 90°,	40	"
	Tinct. vanillæ,	2	"
	Aquæ,	30	"
	Syr. simpl.,	60	"
M.	Dose, ʒj. to ʒij.		

—There are many English-speaking students of medicine in Vienna, mostly Americans; and the fact that certain of the "Privat-Docents" are giving their courses in the English language may, perhaps, be taken as a forecast of what will be the language of the future. It appears, also, that Vienna has no intention of resigning her position as the Continental centre of medical teaching.

—A gold medal, bearing on one side the portrait of Privy Councilor A. W. Hofmann, the well-known chemist of Germany, and on the reverse the inscription, "To A. W. Hofmann, from his friends and admirers in the United States of America," has recently been presented to Professor Hofmann, in remembrance of his last year's visit to America, and in recognition of the services that he has rendered to science.

—At Moscow, epidemic and infectious diseases of all kinds appear to be raging. Between May 11 and June 8, *i. e.*, four weeks, there were no fewer than 1,370 cases in a population of 612,000, including 74 of typhus, 135 of typhoid, 339 of relapsing fever, 46 of small-pox, 69 of diphtheria, and so on. Such an amount of reported cases of typhus and relapsing fever, to say nothing of enteric and diphtheria, bespeaks a very bad state of things among the poorer classes of the community.

—The Minister of Instruction of Germany, Herr von Gorster, received recently an address from German societies for the protection of animals, in which vivisection was said to be necessary, but that vivisection, carried on simply for amusement, ought to be forbidden. The minister replied that he had received the address with great interest, and that it was of considerable value to him to have the opinion of so many societies for the protection of amimals.

—There is a movement now on foot for substituting animal lymph instead of lymph from human beings for purposes of vaccination. The magistracy of Berlin have been collecting information from all the chief German and foreign towns as to the measures adopted for obtaining good animal lymph, and they are likely soon to come to a conclusion, whether it is possible to obtain good lymph in sufficient quantity from healthy calves.

—Fresh advantages are now to be given to the study of dentistry at the University of Berlin. A large building has been given up as the Royal University Clinical Hospital for Diseases of the Teeth and Mouth, under the management of Professor F. Busch, assisted by Dr. Laver and Dr. Klingelhofer. It will be opened next term. A special dental school is also to be opened in the winter term at the University of Leipzic, under the management of Professor Dr. Hesse.

—MM. Beaunis and Mangin, in a note to the Académie des Sciences, "On the Respiration of Leaves in Darkness," state that the belief, that more carbonic acid is exhaled by leaves, when the temperature is high than when it is low, is an error. According their researches, the relation between the quantity of oxygen absorbed, and that of carbonic acid exhaled, is constant, whatever may be the temperature.

—Dr. Becher, at the Medical Society of Berlin, described a case of acute amaurosis occurring in scarlatinal nephritis, unaccompanied by modification of the optic media, and presenting persistent sensibility of the pupil. Meynert explains this kind of amaurosis by the hypothesis that fibres extend from the nuclei of the oculo-motor nerve (floor of the fourth ventricle), and the portion of the optic tract which traverses the corpora geniculata interna, and their external commissure, to the corpora quadrigemina.

—Dr. Coates showed, in November last, at a meeting of the Calcutta Medical Society, a boy, aged four, who had been admitted into the Medical College Hospital with a considerable enlargement of the spleen in consequence of malarious fever. The patient was pale and feverish. There was a bulging near the centre of the swollen spleen, and the aspirator showed the presence of pus. An incision was then made and a drainage-tube inserted; ten ounces of pus were discharged. There was no constitutional disturbance after the operation, the abscess contracted quickly, and the spleen came down to half its previous size.

—In Professor Kaposi's wards in Vienna the permanent bath-beds are in constant use. Burns, ulcers, and obstinate syphilides, are here treated; in the latter cases, weak solutions of perchloride of mercury may be used with advantage; in the cases of burns, the patients express themselves as being most comfortable; after being in the "bed" a few moments, all pain is lost, and there is no dread of change of dressings, for none are used. Not only does the slough separate and the wound clean, but cicatrization progresses, it is said, more rapidly in the water than under any other treatment.

DEATH.

SEYMOUR—July 14, at Pine Bluff, Ark., Dr. J. E. Seymour, of typhoid malarial fever. He was a graduate of the University of Pennsylvania.

ENTERIC FEVER.*

BY B. H. DETWEILER, M. D.,

Of Williamsport, Pa.

The profession are indebted to Lewis and Gerhard for the pathology of enteric fever, demonstrating that it is not allied typhus, but a disease as specific and well defined as variola or scarlatina—and to Dr. G. B. Wood for its clear nomenclature. It is a zymotic disease, and I shall demonstrate the feasability of its being stamped out as readily as variola by vaccination. The exciting cause is the enteric germ, produced by decomposition of alvine discharges of enteric patients. The mode of infection is not by contagion, but by absorption of the germ either by food, potable water, or gaseous emanations. I shall not dwell on its entrance into the system by food or potable water, but by inhalation of the enteric germs. They may be derived from sewer gas or exhalations from alvine dejections thrown on the ground or closet. The most notable case of enteric poisoning by sewer gas was that of the Prince of Wales from exhalation from an old obstructed sewer. The cases related by Dr. Murchison at the school at Clapham, England, where 20 boys out of 22 watched the cleaning out of an old obstructed drain, which had been opened two days before the first boy was taken sick, and the contents spread over a garden adjoining the boys' play-ground. Two of the boys died, post mortem evidence showing enlargement of the glands of Peyer, and the solitary glands; statement made by Drs. Latham, Chambers, and Watson. The recent epidemic at Princeton, New Jersey, closing up the college a short time, and causing the death of many promising young men, was caused by the drainage of the Institution into a large pit without ventilation. Disinfection answered all purposes, and it is no longer a cause of fever. An epidemic in this county in August, 1881, originated at Stony Gap, and is such a clear manifestation of the absorption of the specific poison of enteric fever, that I will describe it in detail . The Gap is four miles from Cogan Station, on the road to Salladysburg. A camp-meeting was held on a spur of the Alleghenies, in a wood which sloped to the east and south. At the foot of the ridge a branch of Hoagland's run passed; at right angles a road crossed the run to a farm house; below the road the spring was located, just above the run from which the drinking water was obtained. Along this ridge in the woods the tents were pitched. The last tent on the ridge was occupied by Mr. Wurster and family, whose youngest son, a young man who had been ill for a week or ten days, camped with his parents. This was on Thursday. On Thursday night he was taken suddenly ill with free alvine dejections, which were thrown out on the ground back of the tents well up on the hill. In the morning Dr. Cline, of Salladysburg, saw the patient, directed his removal to his home, which was done on Saturday, directing them to bury all discharges. He had a regular attack of enteric fever, which had been endemic on Pine run and Larry's creek, for some years. On Sunday following was the great day, when from three to five thousand people gathered at the camping ground from a radius of twenty

*Read before the Lycoming County (Pa.) Medical Society.

miles. The season was unusually dry, with high temperature, and the springs and streams unusually low; winds from the west. The majority of the people did not stay on the ground over four hours. Some drank of the spring water, others neither ate or drank while there. Dr. Howell, of Cogan Station, states that within ten days after this meeting he had over fifty cases of enteric fever; all of whom stated that they had been at the camp-meeting, many of whom neither ate or drank anything on the grounds. From these centres the fever radiated through the households, until he directed the families to thoroughly disinfect the dejections with carbolic acid. He ordered carbolic acid to be placed in the vessel as soon as emptied, and in this way not only disinfected the stools, but prevented any further extension of the fever. No precaution was taken with the discharges after being disinfected, but placing them in the closet used by the family. In one case where this precaution was not used, the family of Mrs. H. Champion, of Crescent, is particularly unfortunate. One of the family was taken sick after the meeting at Stony Gap, followed by one of the younger children; the one taken first died, the second passed through a long, slow convalescence. For seven weeks the disinfection was carried on with success. As the child improved the mother discontinued the disinfectant, and in ten days the fever attacked two more of the family, one of whom died. A full disinfection was then continued until convalescence was restored, and the family had no further accession to the fever record.

At our hospital we have had at different times enteric fever, but with the use of disinfectants by the attendants, with our over-filled closets, we have never had any extension of the disease to either patients or attendants. The poison of enteric fever must be in the dejections, or the emanations will not cause a true enteric fever with the fever of invasion and the fever of ulceration. Some well-defined cases of the fever of foul emanations have just been discharged from our hospital from the McIntyre coal-fields, where there are a large number of Swedes at work. Most of the residents of McIntyre are supplied with water from a spring, brought a distance in iron pipes. The Swedes live in large blocks or houses in tenement style. The houses are level with the street in front, but about five feet above the ground in the rear, without cellars. Under these houses the cows and pigs find shelter, and all refuse matter and dejections are thrown. The Swedes get their water from wells; one is situated between these houses. The street is about sixty feet in width. At the rear of one of these blocks, near the well, a trough with drain was built, into which all refuse from the house was thrown. This was obstructed. It was so offensive that Dr. Bullock, the company physician, prohibited the use of water from this well. In the house to which the drain was attached, there were six Swedes ill with a low form of fever. In the house next to the well, on the north, at an interval of sixty feet, there were two Swedes sick. Five were brought down to our hospital, who had morning remission and evening exacerbation, with elevation of temperature; but not the pathognomonic signs of enteric fever, but merely a zymotic fever from filth. Of those treated at McIntyre, one died from hemorrhage of the bladder, another had hemorrhage of the bowels, but not the specific ulceration of glands of Peyer, nor the copious diarrhœa following these fevers. Nor was it continued with fresh infections, after the drain was removed and thoroughly disinfected.

I mention these cases to show that the surroundings were favorable for a severe invasion of enteric fever. There was some diphtheria. The point I wish to impress strongly is, that enteric fever is a disease *sui generis*; it must have the germs of enteric fever to generate itself. These germs are not active in fresh alvine dejections, and if fully carbolized are innoxious; and the thorough disinfection of enteric stools will stamp out of the zymotic diseases enteric fever, as fully and effectually as vaccination will stamp out small-pox.

DOES DEATH STING?*

BY GEORGE L. BEARDSLEY, A. M., M. D.,
Of Birmingham, Conn.

The dread of dying is quite as intense as the instinct of self-preservation. Indeed, it is not improbable that numbers would care less about living, were the modes of leaving the world a theme for happy contemplation, or an innovation to the routine of plodding, that was agreeable. One is remarkably exempt from the crime of hasty induction, if he affirms that there is no sane or healthy mortal who anticipates his extinction with any degree of pleasure. This generalization is made in the face of the religious exaltation which is declared by the affected as potent enough or so possessing as to overcome the innate fear of dying. It is almost demonstrable that this religious ecstacy is a species of hysteria—if so, the assertion just made holds good. This horror of

* Read before the "Nous Club," of Birmingham, Conn.

passing into the untried country is mainly explained by the tutored notions of the hereafter. A writer has said that the Christian only demurs about dying—the savage counts it a pleasant journey. Even the brute is to be envied for its immunity from encounters with the harrowing apparitions that often follow fast the soul in its escape from the earthly environment.

But with the moral aspects of death we have no concern. If one can rationalize a conception or frame a hope that will assist him to die serenely, quite loath would we be to dispossess him of the inclination. It is the *purely physical* features of dissolution on which just now we are content to ponder.

The material phenomena of death, that is, the process, independent of the "wages of sin," are much more delectable topics for a review than is ordinarily allowed. In its chemical references, dissolution betrays nothing that is repulsive or allied to suffering. Decay is within the domain of the same law as growth. The two are the termini of that series of evolutions which being involves. Now, the molecular changes in repair are never apparent to the sensory centres. The transit from state to state in the genesis of matter is without the cognizance of the feelings equally after birth as during the intra-uterine captivity. No meter has as yet gauged or determined the individual accretions resulting in a healthy assimilation. In the full fruition of the process one sees the gain, but never can he count the steps, much less is he sensible of the mutations. The germination of a cell is, strangely, so quietly perfected that no tissue can predicate of itself what are its interstitial changes. The function of growing is automatic—the individual renders no assistance, and without the least cerebration or effort of consciousness, is operated upon by forces whose silent combinations can never be registered or criticised. The same physio-chemical energies are concerned in the cataclysm of the cell as in its proliferation; only the reciprocity is uneven, the balance between repair and waste is lost, or rather is in favor of the latter. The function of dying is absolutely vegetative—we fall to pieces like a flower. This very fact, that the process is chemical, confirms us in the conclusion that the final "throe" is as painless, as the inconvenience is nothing to the fœtal pilgrim when he touches on daylight. A moment's examination of the way we are to die will show marks of goodness in our "taking off." The degree of sensibility is proportioned to the integrity of the tissues. An inflammation heightens it; age depreciates it. Any defect in nutrition disturbs the comfort of the individual until the carbonic acid generated in the devitalization of the blood becomes fixed in the cells or is no longer displaced. The sensory ganglia everywhere part with their irritability by virtue of this poison, and cease to conduct currents. The criteria of death are being satisfied, and the process is consummated when this extinction of sensibility prevails at the ultimate filaments. During the progress of this dissolution of the nerve-force, this creeping on of the numbness of death, the individual is rapidly passing into a condition of repose, and instead of torture or pangs, a degree of self-satisfaction oft approaching to enthusiasm is realized. The sensations peculiar to the therapeutical operation of opium, haschish, ether, etc., are not improbably akin to the mental activities of the dying. Barring the hallucinations experienced in the stupor as it gains on the subject, the moribund is familiar with naught that borders on suffering. This carbonic acid has poisoned or narcotized the several ganglia, and reflex productions are interdicted. A consummate analgesia prevails. In short, the notion of pain is forbidden the instant that any stimulus fails to excite a response. The condition to this irritability is that the nerve centre and track be sound. If this vigor vanishes, reflex phenomena are at an end, and suffering, physiologically speaking, is impossible, because of the arrest of the function of the sympathetic.

Fortunately, for a wholesome study of one's demise, there are assurances abundant, from vivisection, the testimony of those who have been restored to consciousness, and the affirmations of the dying, that there is no physical recoil from death. Burney tried hard to resist the efforts made to resuscitate him from drowning, so bewitched was he by his prolonged slumber. Dr. Solander, the traveler, was so delighted with the sensations of excessive cold, that he was the first to lie down in the snow to realize the luxury of such a death. Wm. Hunter was sorry he was not able to "write how easy and delightful it is to die." Infants die as serenely as they breathe, and not a few among the advanced in years treat death as a friend to their infirmities. Hanging is, naturally, rated next to crucifixion, a most distressing procedure. But it is reported of those who have been saved from the strangulation, that the agony promised to be brief, and was rapidly replaced by hallucinations of a fascinating variety.

One would feign believe that the kind God who suffered us to feel no sigh in coming, would take

no delight in turning our farewell into writhing. Nay; he does not quit us at the last. He is our greatest benefactor in allowing us to sleep out of weariness. Death is, assuredly, no tax-collector —its "jaws" are not the clutches of an assailant —there is no "victory to the grave"—the ghost speeds away from us as it entered, with no ruffle. The sense of death, as Shakspeare has it, is most in apprehension. It is the fear of the lonely night, not the throes of nature, that makes the leaving painful. Those who are self-possessed, or who are not racked by unwelcome surroundings, or who are not terrified by a cultivated awe about the damnation bottled up for special misdemeanors, these sink into the embraces of death with a longing for the lull it brings to the heavy heart and jaded muscle. The countenance of those who have died in an instant, as from lightning, aneurism, or pistol-shot, is remarkably placid; and not infrequently is it chronicled of this or that death-bed, that in spite of the violence of the inflammation, the patient met death with ease, because of a "saving faith." It will hardly be allowed that a faith can be "saving" enough to be antidotal to a vigorous pain; but the statement is nice, by way of confirmation of the theory that the real agony of the dying is not the reflex disquiet, but the setting in order for leaving.

> "To die is landing on some silent shore
> Where billows never break, nor tempests roar,
> Ere well we feel the friendly stroke."

HIPPOCRATES AND HIS PRACTICE.*

BY THOS. S. SOZINSKEY, M. D.
Of Philadelphia.

* * * * * *

Whatever may have been the success of the various Æsclepia, that of Cos was destined to make the greatest impress on the medicine of the future. It was the good fortune of this institution to have in connection with it, at the acme of its career, a great author as well as physician. Hippocrates, a native of the island, rendered the fame of the Coan school imperishable, and gave to his fellow-men throughout the world, in all time to come, a legacy of incalculable value. Through this early and great medical writer, his alma mater has been made, in a manner, that of the medical men of all ages. From Cos sprang forth, at the touch of an humble man, a mass of medical knowledge, wonderfully pure and good, which constitutes the main body of the real medical science of our own day.

* * * * * *

It is more than probable that except for a short period at first, the system of treatment pursued by the Æsclepiades varied within wide limits; and it is equally certain that the superstitious element lessened as time passed. Between the principles of practice of Æsculapius and those of Hippocrates there is a very great difference. Those of the former will be given later; but of those of the latter I may say here that they were essentially scientific.

To Hippocrates every disease had a natural cause, and was to be cured by natural means. He was one wont "to consult nature herself about nature," as Bacon has somewhere wisely advised. He did not attribute any morbid condition to any spiritual power, good or bad, and hence in his practice did not resort to conjuration or any related means of cure. Even of epilepsy, the so-called sacred disease, he said: "It is thus with regard to the disease called sacred: it appears to me to be no wise more divine nor more sacred than other diseases, but has a natural cause, from which it originates, like other affections." And again: "Men regard its nature and cause as divine from ignorance and wonder." As regards holding disease to be divinely inflicted, he very properly remarks, "I do not count it a worthy opinion to hold that the body of man is polluted by God."

Not only in the principles of medicine, but in its practice, Hippocrates was wonderfully sound, even when judged from the standpoint of the art in our day. In truth, for extent and profundity of medical knowledge and philosophy, between him and what modern would we think of instituting a comparison? Sydenham has been likened to him, but although I am an admirer of the English physician, I do not hesitate to say that he was neither in breadth nor depth any such man as the Coan. As a writer on the prevention and cure of disease, Hippocrates remains *facile princeps*.

Let it not be supposed that my admiration for Hippocrates is unreasonably great. His works are truly a surprise to even the well-read modern. Very many of the so-called discoveries of recent times may be learned by turning to them. I speak advisedly. I will cite instances.

Thus, of the treatment of open sores, he says: "In these cases no part is to be exposed to the air." Dressings of "wine and oil" and "pitched cerate," are directed to be used.

Again, in treating fractures, in connection with certain splints, he advises that "a soft, consist-

*Extracts from a chapter on "Æsclepia and the Æsclepiades" of an unpublished work. References are omitted.

ent, and clean cerate should be rubbed into the folds of the bandage." And he says: "If you see that the bones are properly adjusted by the first dressing, and that there is no troublesome pruritus in the part, nor any reason to suspect ulceration, you may allow the arm to remain bandaged in the splints until after the lapse of more than twenty days."

Still again, in regard to the reduction of a dislocation at the hip-joint, he says: "In some, the thigh is reduced with no preparation, with slight extension, directed by the hands and with slight movement; and in some reduction is effected by bending the limb at the joint and making rotation."

Here we have the practical side of the germ theory of disease, the permanent dressing of fractures and the reduction of dislocations by manipulation.

I might go on and recount numerous other matters alleged to be new and of which we hear much, but it is unnecessary. I may add, however, a few items of interest.

"Blleed," says he, "in the acute affections, if the disease appears strong, and if the patients be in the vigor of life, and if they have strength." Has any modern spoken more wisely on the subject?

Here is a statement worthy of the attention of unbalanced theorists of our day: In fevers and pneumonia, heat "is not the sole cause of mischief."

He gives directions for the use of affusions with "waters of various temperatures," in "cases of pneumonia," of "ardent fevers," and of other diseases. This treatment he thinks "suits better with cases of pneumonia than in ardent fevers."

In that inimitable book, his "Aphorisms," it is said: "In general, diseases are cured by their contraries." There is no exclusive allopathy or homeopathy or dogma of any kind in that statement; it is the sentiment of a scientific physician.

Medicine was evidently far advanced in the days of Hippocrates, and he was certainly a learned and sensible practitioner of it, even "the prince of physicians," as Galen, I think, has somewhere characterized him, as well as one who did much to make it what he himself pronounced it to be, namely, "of all arts the most noble."

—The University of Heidelberg has been offered the sum of 100,000 marks, on condition that it would admit women to its courses. The offer was refused.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.
Reported by W. H. Seelye, A. M., M. D.

Apoplexy.

The patient was admitted January 7th. He is thirty-one years of age, and married. He was brought in in an ambulance from Chambers street, where he was picked up in an unconscious condition, having fallen down suddenly while walking. He was suffering then with signs from which the diagnosis of cerebral hemorrhage was made. There is no personal or hereditary rheumatic, syphilitic, or pulmonary history. Has not used alcoholic liquors to excess. Has worked in a wine cellar, and while so employed he had an attack of chills and fever. For the past three years he has been gradnally losing strength, and has complained much of pain in the occipital region, which was not relieved by treatment, and of some nausea and vomiting. He has recently passed large quantities of water, and has had to get up several times during the night to empty his bladder, and the urine contains albumen in large quantities, and hyaline and granular casts.

On the evening of his admission his temperature was 99.6.° In appearance he was well nourished. He could not speak, and he opened his eyes slowly. The pupils were narrow, but the right was a little larger than the left. He lay in an unconscious condition, but he recovered sufficiently to try to move his limbs, and it was found that both the lower and the upper extremities on the right side were paralyzed, and he tried to lift the right arm and hand with the left, and succeeded. There was no paralysis of either the upper or lower limb upon the left side. In the right arm and hand, sensation was retarded and blunted, and reflex was abolished, and there was anæsthesia over all the right side.

January 8. The patient's condition has improved somewhat. There is some reflex obtained in the left toe. There is no diminution of reflex in the facial muscles. The pulse is full and slow. There have been no involuntary evacuations from the rectum or the bladder. The bladder was not found to be distended, but the urine was drawn off with a catheter, and it measured about three ounces. It was largely albuminous, and contained muco-pus, and granular and hyaline casts. Patient is very dull, and does not mutter, or protrude his tongue when told to. There is facial paralysis upon the right side, but not on the left.

Gentlemen, this patient presents some interesting features in connection with the subject of hemiplegia. He is a young man to suffer from this malady, and yet his disease is one which is not confined to any age. You will see cases of it occurring in childhood, in adolescence, and in adults of all ages, as well as in those who have passed the prime of life. The first point to which I wish to call your attention here, is the association of renal disease with hemiplegia. I have spoken of this association before, and I told you that hemiplegia was commonly associated, not only with renal disease, but with one other very common condition, and that is enlargement of the

heart, with dilatation of the left ventricle, and not only with this, but with that other condition which is the essential element in both the previous ones, namely a diseased condition of the arterial system, or an arterial degeneration, or a fibrosis, as it has been called. This affects, not only the arteries, but the capillaries also; and it is in connection with this arterial fibrosis that you very frequently find that form of renal disease which is attended with a granular atrophied kidney. And with this interstitial nephritis you frequently find an enlargment of the heart, and especially enlargement with dilatation of the cavity of the left ventricle. Now this man not only presents all of these features, but the catastrophe itself, in his case, has been preceded by what may be regarded as the classical prodromata of apoplexy in this condition. One of the commonest of the prodromata is persistent headache, and you have heard it said that this man has had severe occipital headaches frequently repeated, and that they were not amenable to treatment. He had in fact uræmic headaches, and these uræmic headaches are one of the commonest symptoms of this form of interstitial nephritis.

In making the physical examination, the first point to which I wish to call your attention is the heart. The apex-beat I find is in the sixth intercostal space, and a little to the inside of the nipple line. The cardiac impulse is forcible and heavy, and is distinguishable not only over the region of the apex, but also in the epigastrium. The area of præcordial dullness begins a little lower down than usual. The upper line of dullness begins at the superior margin of the fifth rib, and it extends downwards to the seventh rib, and laterally to half an inch outside the nipple. This increase in the area of præcordial dullness is due mainly to an enlargement of the left ventricle. And when this takes place, you are very apt to have this change in the region of præcordial dullness. There is also here some enlargement of the veins just under the skin of the chest, which is suggestive of some obstruction to the free return of blood in the veinous circulation.

The next thing to which I ask your attention is the condition of the arteries. The temporal artery you see is very tortuous; and this is a sign of senile change in the tissues. And I find upon feeling the radial artery that the pulse is full, and there is an unusual degree of tension, and it is dot easily compressible; and the pulsations are unusually visible not only in the wrist, but above the elbow in the brachial artery, and to some extent in the neck. Now it is in this condition of arterial degeneration, with hypertrophy of the heart and degeneration of the kidneys, that you are very apt to get the accident which has befallen this man.

But you may ask if I am quite sure that this is a case of cerebral hemorrhage, and if there may not rather be a plugging of an artery by an embolus or a thrombus. And this is a reasonable question, because he is a young man and he has heart disease besides, which is suggestive of a cerebral embolism. But I examined his heart yesterday, and I did not find any disease of the aortic valves, nor any murmur or other evidence of vegetations in the heart, and so I was inclined to exclude the idea of embolism as the cause of this trouble. But again you might say that perhaps an arterial thrombus has closed up a vessel of considerable size, and from the resulting anæmia and softening of the brain tissue about it, you have an explanation of the condition in which we find him. It is true that there is a certain degree of probability in both of these suppositions, but no more so than of its being the result of a hemorrhage. It is not always an easy matter to diagnose the cause of a hemiplegia. I have no doubt but that there is an organic lesion here; but whether it is a cerebral hemorrhage or thrombosis or embolism, it is not possible to say with any positiveness. But the fact that you have here, as in the great majority of the cases of cerebral hemorrhage, this association of an hypertrophied heart and degenerated arteries and granular kidneys, which I have told you about, is the principal reason why I believe that a hemorrhage into the brain is the cause of the hemiplegia in this case. But if there were a history of a fit of great anger or sudden excitement, preceding the accident, and if there were cardiac murmurs and hypertrophy of the heart due to valvular disease, or if the accident had occurred during an attack of rheumatic endocarditis, I should then think that there was probably a cerebral embolism.

Now, this case is interesting in another point. It is a case of the apoplectiform onset of hemorrhage. This man fell suddenly in the street as in apoplexy, and he was picked up in a partially unconscious condition, with resolution of all the limbs, and with no wound of the tongue to show that there had been any convulsion. But after he came into the hospital he recovered sufficiently to move the limbs on the sound side, and to make the common gesture which is almost diagnostic of hemiplegia, namely to lift the arm on the paralyzed side with the hand of the sound side. But there was no other evidence of consciousness, and he could not speak. There was anæsthesia all over the right side of the body, and reflex was abolished. Loss of sensibility in connection with loss of motion is not always observed, and in many cases there is loss of sensation which is not accompanied by loss of motion. But here there was both. This is the important point, as it gives us the opportunity of locating with more or less precision the place at which the hemorrhage has occurred. I say with more or less precision, because the localization of brain lesions has not yet been reduced to great accuracy. But the knowledge on this point is approaching precision, and it will probably some day be pretty exact. We sometimes know where the lesion is, for in some particular localities we get special symptoms. It was formerly thought that a lesion in the corpus striatum would produce only a loss of motion, and it was claimed by many that if the lesion was in the optic thalamus you would get, in addition to a loss of motion, a loss of sensation. Others extend this area in which there is loss both of motion and sensation to the pons variolii, where all the fibers which come from the cerebrum are found together. In some cases of hemiplegia the loss of sensation is temporary, while the loss of motion remains. In these cases it is probable that the lesion is small, and so only affects temporarily the centres which control sensation. It

seems in this case probable, from the fact that there is loss of sensation as well as motion upon the right side of the body, that this lesion is in the neighborhood of the pons. And inasmuch as the coma is not profound, but he is in a state of semi-consciousness, I think that there is reason to suppose that the hemorrhage is not a very large one, but is merely of sufficient size to produce a loss of power and sensation, with a partial but temporary loss of consciousness. The loss of consciousness is often very profound, and if it remains so for twenty-four or forty-eight hours, the patient will probably not recover his senses. But if the loss of consciousness is not complete, though it may continue so for many days, there may yet be entire recovery of it.

There is one other symptom noticed here which you sometimes see developed very early, and that is a certain amount of rigidity of the limbs upon the right side. This is present now to a slight degree in the lower limb of this man; but it is usually more marked in the right arm, though it is not so here. But if I attempt to turn his head towards the left side it occasions him pain in the left side of the neck, and there is rigidity of the muscles of the neck upon that side. In some cases this rigidity of the muscles is absent and sometimes it is present, but I do not know why there is this variation. But we may speculate as to the cause of it. It may be due to the irritation provoked by the clot; but this I do not know. It is present in a certain proportion of cases, and where it does not exist there is generally a good deal of pain provoked if any attempt is made to flex or extend the rigid muscles. It affects the flexors, as a rule, more than the extensors. Late rigidity of paralyzed muscles is a very common phenomenon.

In regard to the prognosis of such a case, where the consciousness is not entirely abolished and is incomplete, the prognosis is good that the patient will ultimately recover consciousness, although he may remain in this state for two or three weeks. As to the prognosis concerning the hemiplegia, there is not so much to be said in favor of his recovery. When he returns to consciousness it will probably be found that in addition to the paralysis there will be more or less aphasia. But it is not absolutely necessary that this should be the case, for you sometimes see right hemiplegia with no accompanying aphasia. If the lesion is located far back in the hemisphere, there will not be any aphasia. This morning he spoke a little, and said that he felt very well. So he may recover his speech perfectly; but it is not safe to say so. As to the prospect of recovery from the hemiplegia, I can hardly judge. But he is a young man, and if the clot is not extensive, he may recover the use of the right side to a very considerable degree. For the clot may be so small that it will be gradually absorbed, and the connections between the divided nerve fibres may become re-established, and so he may regain at last the free use of the muscles upon the paralyzed side of the body. However, with this condition of a hypertrophied heart, and atrophied kidneys, and degenerated arteries, this is a rather exaggerated expectation. But you should be very guarded about your prognosis in such a case.

Now as to the treatment. Perhaps, there is nothing more embarrassing to a young doctor than to be called suddenly to a case of apoplexy. The old traditions as to the treatment of this disease still have a pretty strong hold upon the popular mind. Something energetic must be done; and blood-letting and hot applications to the feet, and powerful doses of purgatives and the like, is what is expected by the friends and those who are interested in the patient. And the man who should calmly consider the situation, and only do the little that needs to be done, would be suspected of incompetence. But there is no occasion for any energetic procedure immediately after an attack. Consider the conditions present in this man for instance—the diseased arteries, the hypertrophied heart, and the atrophied kidneys, associated with a hemorrhage into the brain, and a state of partial unconsciousness, with hemiplegia. Now what is there that you can do for his relief? Almost nothing. You may say, why not bleed him? Well, you might, if you were sure of your diagnosis. If you were brought to a man in whom you were in doubt as to the existence of a hemorrhage, but if you found that there was great fulness of the vessels of the head, and that there was albuminuria and evidences of a granular atrophy of the kidneys, and a hypertrophied heart, and a full pulse with irregular arteries, and if you found him lying in a state of complete coma, you would not do far wrong if you should bleed him. These are the cases in which bleeding has gained its great renown, because they so closely resemble the coma of uræmia, where blood-letting is often followed by relief. So though an attack of coma is not necessarily connected with blood extravasation, you will not do any harm by bleeding. But if it is due to a cerebral hemorrhage, you will not do any good, for this will not relieve him from the consequences of the hemorrhage.

Here it would not be necessary to bleed the patient, for he lies quiet, in a partial stupor, and has an easy pulse with moderate tension, and there are no signs of cerebral congestion. And with these signs of cerebral hemorrhage, how are you going to help him any by bleeding? I should even question the utility of purging, though I don't know as it would do any harm. But that is not a very philosophical reason for administering drugs. You can not do much for his relief, and so he may be safely left alone, only giving your attention to proper feeding and to regulating the proper operation of the kidneys and rectum, and all the organic functions.

Empyema.

The next patient is a man 37 years of age, a silversmith, and married. Was admitted to the hospital January 6. His father died of heart disease. The family history is otherwise negative. Patient does not use alcoholic liquors, and has never had any venereal disease. His general health has been feeble for a number of years. Ten years ago he had fever and ague. And then he had frequent bilious attacks, but has not had any of late. He was also very subject to attacks of cardiac palpitation. Seven or eight years ago he had his first attack of asthma, which finally disappeared; and he was not troubled again until twelve months ago, when the asthma re-

turned. There was a panic at that time, and he was thrown out of employment, and he thinks anxiety and worry brought on this attack. He got better, however, but ever since, upon exertion or after becoming fatigued, he has been troubled with shortness of breath. Three weeks ago he took a severe cold, which caused him to cough violently and to raise a viscid, muco-purulent expectoration. Shortness of breath became extreme. and he had a feeling of weight and oppression about the chest. There was no pain or vomiting. He is a moderate eater, and his bowels are regular. His expectoration contains no blood. The shortness of breath and oppression have continued up to the time of his admission, and his feet and legs have become swollen. On admission his pulse was 92, respiration 30, and temperature 102.2°. He passes two pints of urine a day, and it is dark-colored, has an alkaline reaction, and a specific gravity of 1.017, and contains granular hyaline and fatty casts.

Asthma, gentlemen, is a very vague term, as used by patients, and even also as used by many doctors. Strictly speaking, asthma is a nervous dyspnœa, and the term should be confined to that sort of dyspnœa which is dependent upon a spasm of the bronchial muscles. Dyspnœa is often spoken of as asthma where there is no real bronchial spasm. Asthma in the sense of dyspnœa, for these terms are popularly convertible, is something from which many people suffer. Now this patient speaks of having had an asthma lasting a year; and what is important to note is, that he says it began during a panic, when he was out of employment, and he was consequently suffering from more or less anxiety, trouble, and distress. He got better, but note, he did not get entirely well. After unusual exertion or fatigue, and from emotion and other causes, he had more or less difficulty of breathing. What I am coming at is, to say that the dyspnœa here is probably connected with a defective blood circulation; and I suspect that this is dependent upon a centric difficulty, and that when we come to examine him, we shall find some change in the cardiac condition from the normal.

Now the attack for which he came into the hospital dates back three weeks, and the subjective history since is one which points to a weak chest; and now we are to find out by the physical examination wherein this weakness exists.

I find the apex beat in the fifth intercostal space and one inch outside of the nipple line, and I get a mitral regurgitant murmur and a friction murmur besides, and I find evidence of a cardiac hypertrophy. The jugulars are also enlarged and full. To save time, I will tell you briefly what is the condition here, as it has already been made out by a previous examination. The patient has pulmonary lesions of considerable extent. He has a dry pleurisy in the left lung, and there is evidence of empyema upon the right side of the chest. To show this, the doctor will now puncture the chest in the eighth intercostal space in the line of the axilla. It is a good plan before puncturing the chest to draw the skin down tightly over the point at which you intend to insert the needle, so that when the needle is withdrawn the line of puncture in the skin and the muscles will not be the same, and therefore the skin will close over the opening in the muscles, and so act as a valve to prevent a further outflow of fluid, or the entrance of air. You see now the yellowish purulent fluid which the doctor has drawn out with the hypodermic syringe, and it is evident, therefore, from this test, that we have here to deal with an empyema, probably of recent origin. And this it was, no doubt, which gave rise to the symptoms from which he has suffered for the last three weeks. But in addition to this, there has long existed a pleurisy upon the left side, and a consequent embarrassment of the lung from pressure, and a bronchitis and a hypertrophied heart, and albuminuria. And therefore he is laboring under conditions which are decidedly adverse. Now the question arises as to the advisability of treating him for the empyema. It is not a very favorable case for trying it. But we shall keep him here for some time, and as his condition has already improved considerably, I think we will select what is known as the "thorough drainage" plan of treatment. This consists in making two openings through the chest-wall into the pleural cavity, and after evacuating the fluid putting in a rubber drainage-tube, which is perforated at its central portion, through which the discharges may drain and the cavity may be washed out. And with antiseptic precautions and proper dressings, I think we may get reasonably good results. But we cannot expect that they will be as good as they would be in an otherwise healthy man.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Stated meeting, July 14, 1884. Dr. D. A. K. Steele, President.

The following scientific papers were read:

"A Report of a Successful Case of Abdominal Section for Pyosalpynx, Treated by Volkmann's Method," by Dr. F. H. Martin.

"Fracture of the Clavicle, and its Rational Treatment," by Dr. S. W. Wetmore.

"Rhinolithiasis, and Report of a Case of Forty Years' Development," by Dr. Jefferson Bettman.

A Successful Case of Abdominal Section for Pyosalpynx, Treated by Volkmann's Method.

By Dr. F. H. Martin.

Mrs. T., American, married, ætat 27; weight, 200 pounds; no children, yet desirous of becoming a mother; four years ago aborted a three months' fœtus. Consulted the writer one year ago, because of suspected pregnancy. She had many of the symptoms of pregnancy. such as morning sickness, enlargement and pain about the mammary glands, enlargement of the abdomen, etc., although she flowed regularly every month for the four months, that she considered herself pregnant, yet this was scanty. An ordinary digital examination was made, but no diagnosis was made. Advised the patient to call again, which she did in two months. Examination a second time resulted unsatisfactorily in ascertaining the true state of her condition. In consultation with Dr. W. H. Byford, who also made a careful physical examination, he was inclined to pronounce her case one of pregnancy, as the pa-

tient expressed herself that she felt very decided fœtal movements, together with the other characteristic symptoms that were present, although her menstrual flow appeared scantily each month. Five months subsequently was again consulted. In company with Dr. R. W. Bishop, and whilst the patient was anæsthetized, a very thorough examination by bimanual manipulation per vagina and rectum was made. The small, undeveloped uterus was found crowded close behind the symphisis pubis and inseparable from a large firm-walled tumor, about the size of a five months' gravid uterus, occupying Douglas' cul de sac, and extending upward nearly to the umbilicus, and occupying a position a little to the left of the median line. Owing to the corpulency of the patient and thickness of her abdominal walls, it seemed impossible to make an accurate diagnosis. The uterus measured 2½ inches in length.

The patient was again taken to Dr, Byford, and after a careful examination at this visit, he pronounced the malady a fibroid tumor of the uterus. However, with commendable conservativeness, he advised that an operation be delayed, although the patient was suffering greatly from pressure of the tumor on the bladder and rectum, from intense backache and other reflex manifestations. In two months time her suffering had greatly increased, and she implored its removal, or that something radical be done to relieve her.

Operation, May 15. Assisted by Drs. R. W. Bishop, L. L. McArthur, E. L. Hollister, L. T. Potter, S. Black, T. H. Swayne and E. J. Doering. All necessary antiseptic precautions were observed. Abdominal section was made. Incision eight inches in length, extending from quite near the umbilicus to symphosis pubes, omentum firmly adherent to the tumor, adhesions covering a space of three or four inches in diameter, these were ligated and carefully separated. Not until the omentum was separated, was the true nature of the tumor revealed, which proved to be a large dilatation of the left Fallopian tube, with thick, firm walls. Tumor so generally adherent to the surrounding tissue that it resembled a fibroid or other solid tumor. Fluctuation was very indistinct, and only by introducing the needle of an aspirator, were all doubts of it removed. Upon deeper examination, the tumor was found to develop from the left horn of the uterus, on the opposite side of its attachment were the remains of the fimbriæ of the tube and ovary of the left side, the walls of which were muscular in character and very smooth. The operator intended removing the tumor in its entirety, clamping the small pedicle, and attaching it to the inferior angle of the wound; but this was found to be impracticable, for the tumor was so universally adherent to the surrounding tissues, and the intestines were firmly adherent upon almost its entire surface above, the rectum being involved so as to appear almost as if it were part of the tumor; and Volkmann's method of treating abscesses and similar tumors was resorted to, viz., stitching the walls of the tumor or abscess to the peritoneal edges of the abdominal wound, and treating it after union has taken place, as an external abscess. The opening in the abdomen was closed, with the exception of the lower angle, where about three inches was left patulous, the tumor was stitched to the peritoneal edges of the open wound, so that about two inches in diameter of its upper surface remained exposed. The wound, of course, was dressed antiseptically. Examination on the fourth day after the operation revealed the tumor firmly adherent to the abdominal wound. A free incision was now made into the tumor, and a double half-inch drainage-tube inserted sufficient to reach the bottom of the abscess. More than a quart of healthy pus was evacuated; the cavity was then thoroughly cleansed with a two per cent. solution of carbolic acid, and again immediately after with a saturated solution of thymol, to prevent any tendency to carbolic-acid poisoning. Then at night and morning the cavity was cleansed with a solution of corrosive sublimate, 1 part to 3000, and the external wound dressed with corrosive sublimate gauze, 1 to 2000. During the succeeding ten days, the patient's condition was favorable, when the temperature suddenly rose to 102° F. Eleventh day it reached 103⅗° F. Respiration irregular and frequent; pulse 160. Dr. C. Fenger saw the case at this stage; he decided that the lining of the abscess was absorbing purulent matter, which produced the general constitutional disturbance. The opening of the abscess was enlarged by blunt pressure, and the inner surface scraped with a dull curette, and cauterized with a 20 per cent. solution of chloride of zinc. Further search revealed an abscess in the thick abdominal walls, which was opened and drained. After this procedure, the temperature became normal. She continued to improve until the abscess entirely discharged itself, the wound closed, and perfect recovery ensued.

DISCUSSION.

Dr. J. H. Etheridge inquired of the author what his diagnosis was, before, as he stated, "it was confirmed while operating?" He thought the case had been managed in a most consummately skilful manner, and was much pleased to hear the report. This speaker believes that great advancement has been made in treating these cases the past few years, to ward off suffering and save life; and that the disease is extremely common, only we cannot diagnose it. A physician of Denver introduces the whole hand into the vagina of a patient whilst she is under the influence of an anæsthetic, and by conjoined manipulation is rendered more able to arrive at a conclusion in the differentiation of this from other disease of the pelvic cavity. He would also inquire, What was the result of a rectal examination? This gentleman then presented the history of a case of pyosalpynx, and exhibited the pathological specimen removed from a case that had recently been under his care. There is nothing particular that needs to be mentioned about the operation.

The case is the ulterior result of perimetritis, which extended and brought about the salpyngitis. This author stated he had no doubt but what an old gonorrhœa, where it is latent and the discharge scarcely if at all perceptible, was one of the causes of producing it. A long-continued chronic orchitis also may produce it, yet upon inquiry of Dr. A. H. Burr if such difficulty was traced to the husband of the patient of the case he now presented, he was answered negatively.

He now verbally gave the *Pathology* of this case, which, condensed, is as follows :

The right ovary was free from adhesions, and was in a comparatively healthy condition.

The right Fallopian tube was inflamed and enlarged. Its fimbriated extremity was so changed and enlarged by previous inflammation that its fimbriæ were obliterated and the canal stenosed absolutely. It, the fimbriated extremity, was free, being attached to nothing.

The left ovary was imbedded in an accumulation of inflammatory exudate, which involved the broad ligament and tube in an indistinguishable and non-separable mass.

The left Fallopian tube was inflamed and enlarged throughout its whole length. Its fimbriæ were enmassed and indistinguishable. Its canal was patulous, the distal mouth opening into the abdominal cavity. The outer third of the tube was inseparably agglutinated to the upper surface of the ovary. It was impossible for the free end of the tube to be brought in contact with the ovary, because of the obliteration of its fimbriæ, of its universal enlargement, and of the complete encapsulation of the ovary.

A serous cyst, the size of a pullet's egg, was developed in the inflammatory adhesions of the broad ligament and tube. It was a simply serous accumulation from the perimetritic inflammation.

A minute par-ovarian cyst had commenced developing beneath and outside of the broad ligament cyst.

The condition of the tubes showed that the patient was irremediably and hopelessly sterile.

The inflammation and patulous canal (opening into the free abdominal cavity) of the left Fallopian tube constituted the chief source of danger to life. Pus and inflammatory product extruded from the fimbriated extremity, and was constantly liable to start up renewed attacks of inflammation, which would soon have fatally exhausted her. From this source she has had doubtless many minor attacks of perimetritis already, each in turn increasing the exudate which encapsulated the left ovary.

The irritation from incarceration of the left ovary in menstruations is probably what led to the menorrhagias which were progressively anæmiating her.

The pachy-hemorrhagiparous condition of the pelvic peritoneum, which produced an hematocele nineteen months ago, together with the salpingitis, perimetritis, and menorrhagia resulting in progressive anæmia, emaciation, and debility, seemed to demand imperatively the entire removal of the uterine appendages.

She lived but a few days after the operation, and succumbed from the asthenia and hopeless condition existing prior to being operated upon.

Dr. H. P. Newman's experience in these cases was that they are difficult to diagnose and are very troublesome ailments. He thought the successful case as reported was extremely well managed indeed, but I would like to ask the writer to explain more minutely his means of diagnosis during the earlier stages of the disease. The speaker would not attempt to make any extended remarks, for the paper and the gentleman preceding him had stated about all there is to be said upon the subject.

Dr. L. L. McArthur, regarding Volkmann's method. He had seen it carried out in the treatment of three cases of abscess of the liver, and one case of abscess of the spleen, with slight modifications. This was done in the service of the city hospital, and is there approved.

Dr. L. T. Potter inquired if the neck of the uterus was the normal length; and would he have been justified in passing a probe earlier, if the tumor pressed the uterus to such a degree that the uterus resembled this organ containing a fœtus ?

Dr. Martin replied as follows: that he did not discover the exact nature of the tumor until the time of the operation, and not until after he had entered the abdominal cavity and introduced an aspirating needle. Fluctuation was very indistinct. The tumor seemed very dense. The abdominal walls were at least three inches thick, so that great difficulty was had in trying to outline any form of tumor, even by the minutest examination. The cause of it could not be ascertained. He was in doubt for months that pregnancy existed. Thought perhaps one cause of these tumors might be from stoppage of the uterine orifice of the Fallopian tubes. It was utterly impossible to diagnose the case at any stage. Bimanual manipulation through the rectum and otherwise availed nothing. The rectum was adherent in every direction to the (as supposed) uterus or tumor. Other physicians who saw the case from time to time were in doubt, as was stated in the paper, in their diagnosis, and several different opinions were offered by them. He was afraid to manipulate the womb to great extent or to introduce a probe, as she was very desirous of giving birth to a child, and nearly all the evidence showed the uterus to contain a fœtus ; and yet he examined her two or three times before the uterus was found. It was crowded close to the simphysis pubis. The neck of the organ was not in the position it usually occupies when a woman is pregnant. The uterus was the normal size.

Fracture of the Clavicle and its Rational Treatment,

By Dr. S. W. Wetmore, was an unusually carefully prepared and finely illustrated paper. Many of the methods of treating this accident were alluded to. Only two, however, were described minutely and endorsed by him, of which we append the following synopsis :

After a few well chosen remarks by the writer, he proceeded to demonstrate first the method introduced by Dr. E. M. Moore, of Rochester, N. Y., having a student on which to adjust the dressings. As the literature of clavicular fractures is replete with a multiplicity of appliances having for their object the restoration, co-aptation, and retention of the fragments during the process of repair. Surgeons, during the last half century, have very closely followed the teaching of the old masters ; but to introduce the most effective, simple, practical and satisfactory retentive measures is accredited to men of our day.

Causes.—After discussing how fractures of the clavicle are most frequently produced, describing the solution of continuity, etc., etc., he thus continued : If the fracture is complete, the shoulder is depressed and drawn forward by the action of

the pectoral muscles, while the inner portion of sternal fragment is salient, and sometimes perforates the tissues sufficiently to constitute a compound fracture, though happily, this complication rarely occurs. To better comprehend the obstacles with which we have to contend, the reader should be familliar with the origin, insertion and action of the great pectoral and sterno-cleido-mastoid muscles. The peculiarity of the pectoralis major is, that its upper fibers become undermost at its insertion, and its under fibers become uppermost.* That the clavicular fibers of this muscle are direct antagonists of the sterno-cleido-mastoid, and the further the humerus is carried backward, the greater the tension of these fibres, and the more perfect the restoration of the fragments. The elbow figure-eight bandage meets all the requirements in a simple fracture of the clavicle in the middle third, the one we will take under consideration, and by using a shawl or piece of cotton cloth or muslin, folded like a "string necktie" or cravat; it should be eight inches in breadth; this should be about two yards long. Placing this wide folded bandage across the palm of the surgeon's hand, the surgeon then seizes with this hand the elbow of the patient which corresponds with the broken clavicle, the two ends of the bandage hang to the floor, the one falling inward towards the patient is carried upward in front of the shoulder and over the back, making a spiral movement in front of the shoulder. This is entrusted to an assistant; the outer end is then carried across the forearm, behind the back, over the opposite shoulder, and around the axilla. This meets the other end, which may be carried under the axilla, and over the shoulder of the opposite side, thus making the figure-eight turn around the sound shoulder.† Continuing the description, this twist, it will be seen, makes also the figure eight turn around the elbow of the affected side. The forearm should be sustained by a sling, which raises it to an acute angle, in order that gravity may assist in moving the whole arm backward. This is best done by a simple strip three or four inches wide, which may be pinned to the fabric or bandage at the shoulder, or by a sling across the opposite shoulder and behind the back. It will be observed that the bandage as it passes in front of the arm does not press on the axillary border of the pectoral muscle and therefore avoids the objection of the ordinary figure-eight.

The writer has treated a number of cases during the past ten years by this method with no unsatisfactory result, and heartily commends it to the profession. Its advantages are:

1. The apparatus is readily obtained and found in every well-regulated household.
2. It can be applied over the ordinary clothing.
3. It is readjusted easily when it becomes disarranged.
4. Any attendant can be instructed so as to readily keep it in place.

* See any work on surgical anatomy where a dissection of these two muscles is illustrated.—L. H. M.

† The reader can easily follow the description herein stated, by the adjustment of a shawl or a piece of muslin eight inches in width, so that when it is folded upon itself it will be four inches wide, then apply it to any member of his household, over the subject's clothing.—L. H. M.

The next method we will describe is that of Dr. Louis A. Sayre, of New York city, who treats fractures of the clavicle upon the same principle, viz., *putting the clavicular portion of the pectoralis major muscle on the stretch*, and compelling it to pull the clavicle in place by means of adhesive plaster cut in two strips three or four inches wide (for an adult), one piece long enough to surround the arm and go completely around the body, the other to reach from the sound shoulder around the elbow of the fractured side and back to the place of starting. The first piece is passed around the arm just below the axillary margin, and pinned or stitched in the form of a loop sufficiently large to prevent strangulation, leaving a portion on the back encased by the plaster. The arm is then drawn *downward* and *backward*, until the clavicular portion of the pectoralis major is put sufficiently on the stretch to overcome the sterno-cleido mastoid, and thus pull the inner portion of the clavicle down to its level. The plaster is then carried smoothly and completely around the body and secured with a safety-pin to itself on the back to prevent slipping.* The first strip of plaster fulfils a double purpose, first by putting the clavicular portion of the pectoralis major muscle on the stretch, it prevents the clavicle from riding upward; and secondly, acting as a fulcrum at the centre of the arm when the elbow is pressed *downward*, *forward*, and *inward*, it necessarily forces the outer extremity of the humerus (and with it the shoulder) *upward*, *outward*, and *backward*. It is kept in this position by the second strip of plaster, which is applied as follows: commencing on the front of the shoulder of the sound side drawing it smoothly and diagonally across the back of the elbow of the fractured side where a slit is made in its middle to receive the projecting olecranion.

Before applying this plaster to the elbow an assistant *should press the elbow well forward and inward*, and retain it there while plaster is continued over the elbow and forearm, pressing the latter close to the chest, and securing the hand near the opposite nipple, crossing the shoulder at the place of beginning; it is there secured by two or three safety-pins. When this has been done, the deformity will have entirely disappeared, the fractured bone will be accurately adjusted, and as long as the strips of plaster maintain their position, no amount of force can displace them. It will thus appear obvious to any one interested in the treatment of this most interesting lesion that the key to its successful management is in making the clavicular fibres of the great pectoral muscle tense, and keeping them so during the period required for repair. *No method can be successful if the humerus be allowed to maintain a perpendicular position.* The plaster method of retention has some advantages over the "neck-tie" or cravat mode. It is evidently the more secure, firm, and unyielding, at first (very desirable qualities, particularly with children) and the patient presents a more comely appearance when dressed. Its disadvantages are: The surgeon, and particularly the country practitioner, does

* The same rule may apply in this as in the first description by adjusting a bandage to any member of the house to enable the reader to more readily understand the dressing. —L. H. M.

not always have with him the plaster; in hot weather the plaster is apt to excoriate and become irksome and unpleasant; again, if sufficient traction be made upon the humerus to be of utility as a lever, it necessarily becomes tedious to bear, and the patient tires of the constant strain. * * The writer did not feel qualified to criticise very closely the plaster method, each of the two modes herein described have been before the profession for several years. It is to keep before the medical world those remedial measures which the writer's experience has proven to be the most perfect in its results that the subject is brought forth, although not as advancing anything new, which however, should the discussion advance any more modern and better means, he and all of us would gladly prehend. The paper elicited a free discussion, which was participated in by many of the members. Their views set forth may be found as under.

Dr. R. W. Bishop mentioned a case of double fracture of the clavicle that he had recently been called to attend. Upon examination there was found a three-cornered piece of the bone splintered off, that was wedge-shaped, and "turned up" edgewise under the skin, and any method that he devised failed to retain this fragment in position. The case is improving, however, but still under treatment.

Dr. C. E. Webster, whilst visiting Bellevue Hospital last year, upon the invitation of an interne, who is a personal friend, had his attention directed to a number of cases of fracture of the clavicle, and their mode of dressing, none of whom, he thinks, were applied according to Sayre's method. Upon inquiry, I was informed that usually that method was adopted if a patient was first treated in the clinical department, for it was more artistic than any other; but it would soon become loose, and it also excoriated the surface, and the plan devised afterwards for dressing the fracture is similar to that which are doubtless seen frequently by physicians.

Dr. W. L. Axford had listened with great interest to the instructions set forth in the paper on this topic. With the solution of continuity that occurs at the middle or outer third of fracture of this bone there is also deformity of the acromial or sternal fragments, or of both. To treat this, we must raise the outer or acromial end and lower the sternal end, especially the former must be done. So many methods are recommended for treating these cases, that any of them are axiomatic, and the case will pursue its own course until there is recovery. He is therefore skeptical of any of the ways as being superior to any other mode. He desired to ask the author if no deformity resulted in the cases he has treated by the methods he has endorsed?

Dr. A. B. Strong: Regarding the anatomy of the muscles of the clavicular region, nothing has been stated in the paper that the sub-clavias and dense fascia play any part towards adding to the deformity, which I think is true, for this little muscle is excited to contraction, or is irritated, and so to is the dense fascia, as a result of the fracture, relative to the treatment, he thinks to place the arm in a simple sling and have the patient lie on a hard mattress, that as good results will occur; and this he thinks is really the best possible known method. He was much pleased with the paper, as he had not heard of nor had he ever seen the dressing applied before, that the author has so ably commended.

The Chairman. I saw the case with Dr. Bishop, that he has cited; the fracture was comminuted, and there was a tilted edge of spicula of bone that could not be retained in its place. The method spoken of by the writer is not unlike what is called here Dr. R. N. Isham's method, *i. e.* by making a hitching-post of the sound shoulder and begin here to apply a bandage, and form a double figure-eight. It gives as good results as any unless it be a plaster Paris dressing; this, however, is irksome and difficult to apply to little children. His success and experience is that deformity will result, no difference what plan is adopted. The let alone plan often times will do, and nature will give an admirable result; he has long ago discarded the use of the plaster method. A bandage secured to a tight-fitting knitted shirt is another very good way to retain a fracture in its place.

Dr. L. H. Montgomery inquired of the author if a case was presented to him that was similar to the comminuted fracture cited here, where the fracture is oblique, as they always are, which of the methods would he apply, that he has offered? And would it not be necessary to apply also a compress over the seat of injury? My experience in treating these cases is, that all have recovered, so far as I know. Two, without deformity, one of which was the so called "green-stick" fracture, occurring to a little boy 6 or 7 years old. The other case being that of a young man eighteen years old, a clerk, who was anxious that no deformity should result. I told him the only possible method to avert this would be for him to lie on a pretty firm or hard mattress for three weeks, after I dressed the broken clavicle by bandages, and a small bag of sand applied over the seat of the fracture for a compress. This he did for about that length of time, and to our great satisfaction, a perfect result was obtained. I think a compress of this kind is valuable if we can persuade a patient to remain quiet, especially if the patient is a female who is particularly desirous of no deformity.

Dr. W. H. Curtis thinks great caution should be taken to avoid compressing the brachial artery in applying a bandage or plaster dressing tightly around the arm, especially if the surgeon can not be had quickly. Should swelling supervene. the patient and friends should be on the alert for this, which if it occurs the bandage should be loosened and readjusted.

Dr. Wetmore replied serially, first to Dr. Axford, by stating that he had treated a number of cases of this fracture in female children and adults, and no deformity resulted. In strong, athletic men he recalled more than one instance also where by the Moore method of treatment perfect recovery resulted. Twenty-five years ago, he saw his preceptor treat a case of this kind by having the man lie upon a bolster to get the weight of the shoulder to pull back the clavicle. The man recovered with no deformity. In the case of comminuted fracture that has been cited and inquired about, I think a compress applied and Moore's method carried out would be the most judicious dressing.

The next paper was a very comprehensive one on "Rhinolithiasis," by Dr. Jefferson Bettman, of which our reporter has furnished a short abstract, and given the principal points of a case of this rare form of difficulty.

Report of a Case of Rhinolithiasis of Supposed Forty Years' Development.

The comparative rarity of this affection, and the interesting features connected therewith, warrant our giving a synopsis of the following case:

Status præsens.—The patient, æt. 49, consulted the author in June, 1884, for what he termed "chronic catarrh of the head," extending over a period of many years. Of late, the annoying symptoms had been more aggravating. The nasal discharge was so copious as to necessitate a daily use of from four to six handkerchiefs. Periodical attacks of hemicrania extending over the right orbital and temporal regions also complicated the case. Marked obstruction on the right side of nasal respiration. Physically he is of goodly dimensions, well-proportioned, a picture of florid health. External nose appeared congested and slightly tumefied, borders of the nostrils somewhat excoriated. Introduction of the nasal speculum occasions violent attacks of sneezing. This exquisite hyper-sensibility of the mucous membrane quite precluded a thorough examination of the nares. There was limited fetor in the expired breath, yet sufficient as to be imparted to the nasal secretion. This was viscid, slightly flocculent, and filled both nostrils, necessitating removal ere permitting a survey of the parts. Illuminating the nares, a marked vascularity and thickening of the mucous membrane was noticeable. The tissues covering the inferior turbinated bones were so thickened as to encroach upon and nearly obliterate the fissura respiratoria.

The mucous membrane covering the septum presented almost a fungoid appearance; both middle turbinated bones were enlarged so as to press upon the septum. The posterior half of the right nasal fossa was filled with an accumulation of creamy-looking discharge, and attempts at its removal by a well-directed stream of tepid water were futile. The nasal lumen was so narrowed and encroached upon by the hypertrophied turbinated bone and a co-existing deflection of the septum, that it was with difficulty a cotton-wrapped probe could be guided through the parts that were so sensitive. Palpation revealed the presence of a hard grating substance occupying the floor of the right nasal fossa, which was supposed to be necrosed bone as a result of a constitutional dyscrasia. Thorough inquiry elicited negative replies in this direction. To allay the morbid sensibility of the parts, a detergent nasal lotion was advised to be used *ad interim*. In two days this proved effective, for the hyper-sensibility and tumefied mucous membrane were markedly improved. Under a strong illumination, the position of the foreign body was then defined. Lying on the floor of the nasal fossa in its posterior half, it seemed to be impacted between the bony septum and inferior turbinated bone. The exposed surface of body was rough, uneven, unyielding to the touch of the probe. To dislodge and remove it, a pair of strong aural forceps, bent at right angles, were used. A firm resistance was made upon traction. The fauces, too, were uncontrollably irritable, defeating all attempts at posterior rhinoscopy. The size of the body had undoubtedly been underestimated. Its removal in toto anteriorly was impossible, on account of the narrowed lumen of the nasal passage. Attempts at removing it piecemeal were but partially successful, after repeated trials. The feasibility of removing it through the naso-pharyngeal space presented itself. Cautioning the patient not to inspire deeply, or swallow, while the operator guarded the faucial orifice, the foreign substance was then forced into the naso-pharyngeal space, and in a moment the gentleman spat it out. Darkish-gray, almost black in color, conoidal in shape, and from which a disagreeable fetor emanated, its weight, firm consistency, and the pebble-like uniformity of its unexposed surfaces, were sufficient to indicate its calcareous condition. Irregular in shape, the contour of the concretion conformed to the confines of the surrounding tissues. Its medial surface measured one and a half centimeter in length, by one and a quarter centimeter in breadth; the inferior surface one and a half by one-half centimeter. The exact weight was one and a half grains. Embedded in the mass was a cherry-stone. Incidents of the patient's early childhood were vividly impressed upon his memory, but in no possible manner could the presence of the cherry-stone be accounted for. Free nasal respiration was fully restored, and great relief followed. Subsequently, however, a small mucous polyp, high up in the same nostril under cover, and almost hidden by the middle turbinated bone, was discovered, which was easily removed.

The literature on the subject of rhinolithiasis was then carefully reviewed by the writer minutely. Stœrk avers that he has seen but one example of it, and no mention of it is made in many works on general surgery. The term was first applied by Demarquay, and our French confréres describe the greater number of cases. Demarquay and Poinsot have written brochures on this subject. The determining cause is the presence of a foreign body, which forms a nucleus for the deposition of lime salts. Nasal concretions have, however, developed independently, and were not due to the presence of any extraneous substance, congenital or acquired atresia. Stenoses of the nasal lumen favor the retention, and subsequent desiccation of nasal secretion, and by a nidus, cause a concretion. A gouty diathesis may also be a predisposing cause. Virchow describes a "diathesis ossifica" as a cause, which, by the way, is an entirely different process, however, somewhat like the subject under discussion. During an act of vomiting or retching, undigested particles of food which may be forced through the naso-pharyngeal space and lodge in the posterior nares, may be the nidus. Barring this possibility in the foregoing case, the concretion may be presumed to have been of more than forty years' development. Jacquemart lately described a case where the trouble existed over twenty years.

Multiple rhinoliths have been found in rare instances. Their concentric disposition was next described by the writer, which consumed considerable space; also their chemical composition.

The symptoms incited by their presence are frequently not marked, and hence they are doubtless often overlooked. The rhinorrhœa being regarded

and treated as a catarrhal congestion of the tissues, which may often result in epistaxis, "the chronic vascularity induces a state of hyper-nutrition and cellular activity in the surrounding tissues, favoring redundancy and neoplastic changes."—(Billroth.)

Hemicrania or nervous headache is a noteworthy symptom that is present in many cases. "This may be periodical—and checked by spontaneous expulsion of minute concretions."—(Axmann.) Also, other "reflex neuroses may be present."—(Hack.) The dental drill might render signal service. Posterior rhinoscopy occasionally renders valuable service in their detection. In Jacquemart's case, already alluded to, himself and more than ten consultants had made a previous diagnosis of osteo-sarcoma. A few cases are on record in which rhinoliths were expelled spontaneously where the concretions were very small. A stream of hot water injected through the opposite nostril may in some cases prove effective in dislodging the concretion. "Sternanutatories may be worthy of trial."—(Frankel.) In post-nasal extraction of a calculus, strict precautions must be adopted to prevent it from falling into the larynx.

The remainder of the paper consisted in the laudation of modern nasal surgery, which has assumed a dignified position in the scientific field, but, as the writer justly stated, it is doubtful whether any part of the body is dealt with in so slip-shod and culpable a manner as the *naso-pharyngeal cavity*, and the humane precautions so often neglected in treating nasal disease, on part of both patient and surgeon.

DISCUSSION.

Dr. F. O. Stockton stated that one simple method the essayist had omitted to state in his paper—it was of strong pressure through the posterior nares, to expel the calculus by the anterior nares. Do not close the oppposite nostril, while essaying to do this, which is far preferable to any other mode, when it can be done. Another way is by a simple loop of iron wire passed about the stone, then, by rotating it about the the stone, extract it anteriorly. He cited a case that came under his care whilst he was in London —that of an English gentlemen having a rhinolith, where it had absorbed and passed through some of the small bones of the face. His method of extracting it was by using an engine with a diamond-pointed drill. A hole was drilled in different directions in the stone, and thus it was removed piece-meal He knew of no other case being operated on in this manner. The engine is the invention of Dr. Goodwillie, of Philadelphia, and used by him in dentistry.

At a late hour, the Society then adjourned.

L. H. M.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Staining of Koch's Bacilli.

The *Med. News*, May 1, 1884, says: So much has been written and printed since Koch's original publication, upon the treatment of tubercle-bacilli with a view to their better and easier demonstration, that a systematic article by Fränkel, published in full in the *Berliner klin. Wochenschrift* for March 31, will be welcomed by physicians, especially as the methods are intended to be employed in the office rather than in laboratories.

In general, it may be said of the bacillus tuberculosis that it imbibes only certain aniline coloring matters; that a certain period of exposure is necessary; and that it must be treated by certain additional fluids to secure the most distinct demonstrations.

After a comparative trial of twenty aniline colors, Fränkel concludes, with other investigators, that the best are, undoubtedly, methyl-violet and fuchsin. Both of these are hydrochloric acid combinations, and both stain animal fibres more easily than vegetable. As to the time required for staining, ten minutes are necessary at the temperature of the room, although a much shorter time suffices in the warm box, while Rindfleisch has also shown that by warming the fluid the staining may be made instantaneously.

With the added fluids, Fränkel found the aniline water, as first suggested by Ehrlich, to give the best results, although equally good results were obtained with toludin water, an analogous substance which is always found to accompany the commercial aniline as an impurity. A durable fluid is composed of 93 c.c. of water, 3 c.c. of aniline oil, and 6 c.c. of alcohol. In this aniline water the coloring matters may be dissolved, but it is better to have on hand alcoholic solutions of fuchsin and methyl-violet, and before using to add, by means of a dropper, as Ehrlich originally suggested, as much of the solution of coloring matter as will produce a decided opalescence in the fluid. Five cubic centimetres of aniline water are heated to boiling in a test-tube, poured into a watch-glass, and the concentrated solution of coloring matter added. Upon this the covering-glass, on which the sputum is smeared, and dried by passing it a few times over the flame of an alcohol lamp, is floated for from two to five minutes.

In order to demonstrate the bacillus more distinctly, acids, alcohol, and watery solutions of other aniline colors are used, either to decolorize the other elements of the sputum, cells, nuclei, other fungi, or foreign substances, or so to stain them by these colors as to put them in contrast with the stained bacilli. For this purpose, Ehrlich uses nitric acid diluted three times; Petri, glacial acetic acid; Rindfleisch, feebly-acidulated alcohol; and Koch, in the beginning, vesuvin-solution.

Fränkel regards it as especially important to re-stain the decolorized preparation, thereby elim-

inating all possibility of a mistake. For this purpose he has recently used a mixture of 50 parts of alcohol, 30 of water, and 20 of nitric acid, which is saturated with ethyline blue, and then filtered. Into some of this fluid, the preparation is carried directly from the first color solution, and in this way the decolorization and second staining are at once accomplished, an immersion of one minute sufficing. The sputum on the cover-glass is then washed in water or in 50 per cent. of alcohol acidulated with one per cent. of acetic acid, and well dried by first compressing between filtering paper, and then quickly passing through a flame. In this way, says Fränkel, a preparation can be completely made and doubly stained in four minutes.

Baumgarten's method of demonstrating the bacillus unstained is less satisfactory. By Gibbes's method of staining the bacilli red and the background blue, by a single fluid, Fränkel thinks fewer bacilli are brought out than by the one detailed.

As to the use of an immersion system and Abbe's illuminator, Fränkel says that much time is saved by them; but that with a good Hartnack No. 7, or any corresponding power, and ordinary illumination, the bacilli are easily recognized.

Compensatory Hypertrophy.

Before the Medical Society of London (*Lancet*, April 12, 1884): Dr. Joseph Coats (Glasgow) read a paper dealing systematically with hypertrophy of the various organs. In some preliminary remarks he observed that it was necessary to bear in mind the difference between hypertrophy and hyperplasia, though it was not possible to carry the distinction into practice. Practically it was sufficiently accurate if under the term hypertrophy we included all forms of increase in the quantity of functionally active tissue of an organ, whether this was due to numerical increase of the elements of the tissue or to an increase in the bulk of the individual elements. Compensatory hypertrophy occurred most readily during the period of growth; the causes by which it was produced were of two classes—excessive performance of normal function, and destruction of portions of tissue resulting in overgrowth of the remaining portions. After referring to hypertrophy of the heart, bladder, and various parts of the alimentary canal, he discussed at length the occurrence of hypertrophy of one kidney after the removal of the other, quoting the experiments and conclusions of Rosenstein, Grawitz, Israel, and Gooden, and relating some observations of his own. The general results of these researches seemed to establish that the glomeruli were not increased in number, and not greatly in size (the increase being in the proportion of 41 to 30 or 8 to 5, according to various observers), but the enlargement was chiefly due to an increase in the thickness and bulk of the epithelium, but chiefly to increased length, and therefore increased convolution of the tubules. This, he thought, went to support the theory that the convoluted tubules discharged the most important functions of the kidney. In dealing with the subject of hypertrophy of the lungs, he quoted the researches of Dr. Theodore Williams, and detailed a case of vicarious hypertrophy of one lung from defective development of the other. After a full discussion of this subject, in which he observed that compensatory hypertrophy rarely occurred in phthisis, probably owing to the general depression of nutrition, he shortly referred to the occurrence of hypertrophy of the liver secondary to destructive disease, and observed that it was due to enlargement of the lobules from multiplication of the hepatic cells.—Dr. Douglas Powell differed from the author in respect of compensatory hypertrophy, as it was seen in phthisis; he considered that in such cases hypertrophy could occur. No doubt in some instances the lung remaining did not become hypertrophied but only dilated, and then the patient was breathless and weak. Hypertrophy of organs beset us in all directions. Instances in the heart and stomach were mentioned. —Dr. Fancourt Barnes spoke of the hypertrophy of the heart in pregnancy as a typical example of physiological compensatory hypertrophy.—Dr. Kingston Fowler alluded to cases of hypertrophy and dilatation of the ascending colon associated with ulceration, but no obstruction. Was there general cirrhosis in the case of syphilitic hepatic disease?—Dr. Joseph Coats, in reply, thought that he had admitted in the paper the possibility of the occurrence of compensatory hypertrophy in cases of chronic phthisis. In diabetes insipidus he considered that all the secretory structures were at work, and so tended to become hypertrophied. There was no general cirrhosis in the instance of syphilitic disease of the liver which he had mentioned. He had no experience of cardiac hypertrophy in pregnancy, but regarded the line between physiology and pathology as by no means a hard-and-fast one.

Ipecacuanha in Large Non-Emetic Doses in the Treatment of Cholera.

The *Med. Times*, August 9, 1884, says:

Among the numerous plans of treatment that have been recommended or actually adopted in the treatment of true or Asiatic cholera, there is none that, from past experience, seems more deserving of a faithful extended trial than that by ipecacuanha, as presented to the profession with such force and ability by Surgéon A. A. Woodhull, U. S. A.* The method of treatment of dysentery which was advocated by the author, by "large non-emetic doses," has become widely known and is generally practiced, but the fact seems not to have been properly appreciated that he also insisted upon the possible value of this method of treatment in Asiatic cholera, the full title of his essay being "Clinical Studies with Large Non-Emetic Doses of Ipecacuanha, with a Contribution to the Therapeusis of Cholera." Without attempting an analysis of this valuable paper, we merely repeat the caution of the author, who especially enjoins upon those who adopt the treatment in their practice to adhere to the non-emetic method. Large doses, from a scruple to a drachm of the powdered root, may be given without disturbing the stomach, if the patient remain quietly in the recumbent posture after its admin-

*In a report to the Surgeon-General in October, 1874, which afterwards appeared in full in the *Atlanta Medical and Surgical Journal*.

istration and abstain for a time from drinking fluids. Very often, however, it is necessary to insure the desired result by the preliminary administration of a full dose of laudanum. The strikingly favorable results thus obtained by the administration of ipecacuanha in dysentery, in hemorrhage, and in collapse, would certainly warrant the further extension of this treatment to analogous conditions occurring in the course of cholera. Nor is the recommendation for its employment in cholera without support from clinical experience. M. Bourdon, in the wards of La Charité, has used it with decided success in the treatment of cholera infantum, which so closely resembles the true cholera. In fact, it was reported by M. Decugis (mentioned by Woodhull) that at the first appearance of the cholera in 1832, the physicians, struck by its resemblance to dysentery, proposed ipecac, and it was even considered a specific for cholera by Grisolle; but further experience taught that, when used in the ordinary way, it was of slight utility, and this opinion is generally echoed by our text-books.

The treatment of Dr. Woodhull is, on the contrary, based upon the effects of ipecacuanha when administered in a very different manner, in large non-emetic doses, in which it acts as a sedative, as pointed out by Waring, who also recommended its use in cholera.

A Monstrosity.

Dr. J. H. Gardiner, in the *Canadian Practitioner*, May, 1884, says:

"I have in my possession a remarkable specimen of monstrosity, consisting of a child with two heads, complete and well formed in every respect.

"The mother was in the ninth month of gestation, when labor pains commenced, and the labor did not last more than three hours. She is the mother of four children, all healthy and well formed; both father and mother are healthy. Pulsation continued in head last born, and in body, for more than twenty minutes after birth, and an attempt was made to set up respiration, but it was only partially successful. The head first delivered never showed any signs of life after complete delivery, being very much congested at birth. One hour elapsed between delivery of first and second head.

"There was one cord and one placenta.

"The specimen weighed eleven pounds at birth.

"There was a complete separation of necks down to shoulders, and separate spinal columns to termini.

"The upper extremities are well formed and two in number.

"The lower extremities are deformed, talipes varus existing in all. There are three legs, two in the usual position, and one over right ilium. This third leg is most deformed of all, being smaller and more like a wing without feathers than a leg; there are six toes on it. Two anal canals exist, but the genital organs are of the usual appearance of those of a healthy male child.

"The mother did not complain of any unusual sensations, impressions, or longings, during gestation, nor had she any fright. Now, the question is, how did such a monstrosity have an existence? Evidently twins were designed by nature, and from some peculiar placing of the double ova in early fœtal life, a blending of the parts resulted. The external blastodermic membranes have suffered less than the middle and internal; but I must leave to more skillful physiologists and embryologists to explain this medley on the part of nature. (It reminds me of Dr. Richardson's chicken without the feathers.)"

Reviews and Book Notices.

Notes on Current Medical Literature.

——In a reprint from the *American Practitioner*, Dr. N. B. Cook relates the recovery of a patient who had swallowed two drachms of extract of cannabis indica. In the course of his article he makes the following general remark: "From my experience in the treatment of poisoning from narcotics, if all the remedies recommended were placed before me and I was obliged to select and rely on one only, I would unhesitatingly choose the battery. I would rely on it with more confidence in a good result than all others combined; premising, however, the use of emetics or stomach-pump in cases seen before the poison had all been absorbed."

——The Illinois State Board of Health has issued a circular to all mayors or presidents of village boards of health, recommending that they pay especial attention during the summer months to the following points of public hygiene:

First—The condition of the water supply.

Second—The disposition of night-soil, garbage, and sewage.

Third—The cleansing of streets, alleys, and other public places.

Fourth—The supervision of food supplies, and of market-places, slaughter-houses, and similar establishments.

Fifth—The general sanitation of every house and its surroundings.

——The "Proceedings of the First Three Meetings of the Surgeons of the E. Division of the W., St. L. and P. Railway" (Fort Wayne, Ind.), makes a neat pamphlet of 116 pp., containing a number of original articles of value to surgeons in general, and railroad surgeons in particular. Such a publication is a proof of the enlightened activity of the American profession, and the thoroughness with which it pursues special scientific inquiries.

——The address of Dr. L. Woodruff, of Alton, Ohio, before the Alumni Association of Starling Medical College, is a sensible and well-prepared paper on the relations of medicine to the general public.

——The question of quarantine is discussed temperately in a pamphlet, "Quarantine and Commerce: How to Enforce the One without Detriment to the Other," by Dr. Joseph Holt, President of the Board of Health of Louisiana.

——Dr. Rollin R. Gregg, of Buffalo, New York, sends us one of his novel studies entitled "The Revelations of Fibrin; Unexpected Proof of the Immortality of Life." We fear his experiments will not engage the attention he asks for them.

——The Second Part of Lloyd's Quarterly, "Drugs and Medicines of North America," treats of the Hepatica and Ranunculus. It is well printed and illustrated, and in time must prove a useful book.

——Dr. J. H. Voje, of Fredonia, N. Y., favors us with a copy of his inaugural dissertation on receiving his degree of M. D., at Leipzig. It is entitled "Ueber die Ursachen des sogenannten Puerperal Fiebers," and is a careful thesis.

BOOK NOTICES.

Diseases of the Throat and Nose. Including the Pharynx, Larynx, Trachea, Œsophagus, Nasal Cavities, Naso-Pharynx, etc. By Morell Mackenzie, M. D., London, Consulting, late Senior Physician to the Hospital for Diseases of the Chest and Throat. Vol. II. Philadelphia, P. Blakiston, Son & Co. (Price, 2 vols., cloth, $6.00.)

Dr. Mackenzie has long been considered the leading English authority on nasal and pharyngeal diseases, and this work may justly be considered the summary of his experience and his observations. He tells us that every page has been written and re-written to bring it up to what he considered the proper form, but that even yet he does not reach the ideal he had set for himself. Few place their ideals so high, and fewer are so frank about their endeavors to reach it. Not many readers will perceive where it falls short. Certainly no more complete treatise on the subject is to be found in any language. It will be sufficient to give an idea of the scope of the work, to give a short abstract of its contents:

The Gullet—Anatomy, Examination, Œsophageal Instruments, Diseases, Acute Œsophagitis, Phlegmonous Œsophagitis, Ulcer, Varicose Veins of the Gullet, Malignant Tumors of the Gullet, Non-Malignant Tumors, Syphilis of the Gullet, Dilatations, Rupture, Wounds, Foreign Bodies, Œsophagotomy, Spasm of the Œsophagus, Post-mortem Softening of the Gullet.

The Nose—Anatomy, Rhinoscopy, Nasal Instruments, Acute Nasal Catarrh, Purulent Nasal Catarrh, Hay Fever, Chronic Nasal Catarrh, Chronic Blennorrhœa of the Nose and Air-Passages, Bleeding from the Nose, Tumors, Fibrous Polypi, Malignant Tumors, Syphilitic Affections, Glanders, Affections of the Nose in Eruptive Fevers and other Acute Diseases, Fractures of the Nose, Dislocation of the Nasal Bones, Foreign Bodies in the Nose, Congenital Deformities of the Nose.

The Naso-Pharynx—Chronic Catarrh of the Naso-Pharynx, Dry Catarrh of the Naso-Pharynx, Fibrous Polypi of the Naso-Pharynx, Malignant Tumors, Throat Deafness.

Appendix—Special Formula for Topical Remedies, Nasal Washes, Nasal Sprays, Gossypia Medicata, Olfactoria, Snuffs.

It will be seen that the field is well covered in this volume.

Transactions of the Missisippi State Medical Association, 1884. 8vo., pp. 190.

Quite a number of interesting articles fill this volume, dealing with practice, surgery, obstetrics, and hygiene. While a portion of them are local in character, the greater number will have a general interest for the profession at large, and will merit preservation in print.

The Formation of Poisons by Micro-Organisms. A Biological Study of the Germ Theory of Disease. By G. V. Black, M. D., D. D. S. I vol., pp. 178. Price $1.50. P. Blakiston, Son & Co., Philadelphia.

Many readers would like a clear historical and scientific sketch of the "germ theory," what it means, who started it, what there is to be said for it, what may be its applications in medicine and hygiene. They will find such a sketch in this volume, by a writer who has evidently kept himself acquainted with the progress of the discussion, and who writes without any undue bias for or against, and with an appreciation of what the laws of evidence demand. We do not doubt the essay will prove a satisfactory one to readers, and we recommend it to their attention.

—In the *Edinburgh Med. Jour.*, Aug. 1884, Dr. C. Clark Burman reports a case of abdominal wound, with protrusion and wound of small intestine, the result of a stab. Recovery.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

OCEAN-BATHING.

"If I were to go in the ocean and bathe for half an hour, my pulse would drop from eighty down to forty-five beats a minute." "I feel dreadfully to-day; I remained in the ocean more than an hour, and when I reached my bath-house, I was too much exhausted to dress and felt like lying down and going to sleep." "I had a very peculiar case to-day; a robust young man went in to bathe, and when he came out, laid down in his drawers and undershirt to rest, with two windows open and a current of air blowing over him; in a few minutes he had a violent chill, followed by a raging fever."

These three remarks, overheard within an hour, the other day, are but samples of what one hears every day at our sea-shore resorts. From them it may be inferred that ocean-bathing is not an unalloyed benefit to all persons. Some are so constituted, as the man with the susceptible pulse, that the bath ought to be absolutely interdicted, while with others the evil results are directly traceable to the ignorance or carelessness of the individual. There are very few persons who bathe as they should. The vast majority remain in the water too long, many battling with the breakers for more than a hour, while it is the exception to find a person who remains in less than three-quarters of an hour. One who has never been in the ocean, can form no conception of the amount of force expended in diving into or even standing up against the powerful breakers, involving as it does an amount of labor, of muscular exercise, that would soon produce fatigue, were the surroundings less stimulating and exciting. Again, it is not an uncommon sight to see young men and women, after bathing for half an hour or so, come out of the water and sit on the beach, talking to friends, while the air is rapidly evaporating the water from their persons, and their chattering teeth, livid lips, and shaking bodies, give plain evidence that they are being thoroughly chilled. Then off again they rush into the water, to still further exhaust themselves. A distinguished English physician has said in the *Lancet*, that he believes that if we were to examine the

urine of every person coming out of an ocean bath, in the majority of cases we would find albumen, thus evidencing a temporary congestion, which of course is increased by this exposure and evaporation on the beach. How much better would it be to walk briskly to the bath-house, and disrobing, rub the surface well with coarse towels until a tingling, glowing sensation gives evidence of a re-establishment of the cutaneous circulation! Some young ladies, (though we are glad to say the number is small) are so infatuated with the bath that they will not forego it, even during the menstrual period; that this is wrong, needs no arguments to prove; and still further, some pregnant women actually go in to bathe, and we are not surprised to hear that abortion occasionally results. If a healthy person, not endowed with any idiosyncrasy, which experience indicates as forbidding the bath, will stand about in his bathing clothes until well cooled off (but not long enough to feel chilly) and then go into the ocean for fifteen minutes, keeping the body well immersed all the time, and then rub himself well into a glow, we feel sure that the bath will prove to him an unalloyed benefit, and that he will return from the sea-shore invigorated and benefited by his sojourn there.

MILK DIET.

The recommendation of men distinguished for their talents and with world-wide reputations, has had the usual result with the milk diet question that we are wont to note with all other questions —namely, that the masses, following blindly the few leaders, have gone to the extreme; and we see daily, in the secular press, items to the effect that so-and-so (mentioning some distinguished person) is on the milk diet, and it is generally added that his complaint is Bright's disease. Thus these accumulating reports lend still more popularity to the diet, until in the minds of many persons Bright's disease and milk diet have come to hold a most wonderfully intimate relationship, the one with the other.

That milk is an exceedingly nutritious and easily digested article of diet no one questions, but that it has any *specific* action in Bright's disease seems to us, to say the least, very problematical; while on the other hand, such a restricted diet, serving as a constant reminder to the patient of his malady, would have the effect in many cases of causing the invalid to brood over his incurable disease, and thus by disturbing his equanimity and distressing his mind, would, we fear, have an injurious influence on the progress of the disease. A very distinguished physician in this city, places great faith in milk diet in this and other chronic diseases; and so firmly does he seem to believe in its efficacy, that even though it may sicken the stomach and constipate the bowels, as it not infrequently does at first, he still persists in its use, ordering his patient to bed, and commencing, may be, with teaspoonful doses of milk, with lime water, keeps the patient on his back until the milk ceases to produce these disturbing effects, and can be taken with impunity. But while this process of gradual accommodation may remove some of the objections to an absolute milk diet, it will not do away with the introspective objection which we have urged—it will not prevent the patient from brooding on his disease, and thus helping its progress. It is a fact that we have frequently observed in Bright's, as in other diseases, and it is a fact familiar to all physicians, that in those who are blessed with a buoyant, happy, "easy-going" disposition, who seem to forget (unless reminded of it) that they are afflicted with an organic and incurable disease, the disease seems to make comparatively little progress. We are all familiar with the evil influence of "worry," and of too much concentration of thought upon self and upon one's weaknesses. And from this fact we must perforce draw the logical lesson that we should never advise that which is calculated to cause worry and introspection. Hence, while we recognize the value of milk diet, yet we think that before directing it we should carefully study the temperament and disposition of our patient. To the sanguine, "easy-going," it will, in the majority

of instances, prove an unalloyed boon; while to the nervous, irritable, introspective, and "worrying" patient, it would seem more prudent to recommend the free use of milk, but not to enjoin the absolute, restricted milk diet.

LIFE AT THE SEA-SHORE.

Dr. Busey, of Washington, was offered the opportunity last summer at one of our fashionable resorts, of studying the evil influence of the constant use of high-heeled French shoes upon the female form, and this year we have been favored with the facilities for observing the methods of life pursued at the sea-shore. Without croaking or moralizing or fault-finding, we are compelled, in justice to our convictions, to assert that to the majority of persons a sojourn at the sea-shore is not calculated to prove so beneficial to health as the natural advantages and the intentions of the visitor would seem to warrant. There are two classes of persons who visit the sea-shore: those who go for the whole summer and settle themselves in cottages, and those who go for a few days or a week and stay at the hotels. This latter class, desiring to see and do everything during their limited stay, are on the go from early morning till late at night; they really work harder and consume more muscular tissue than they would do in the same time at home. Consequently their appetites are unnaturally great, and are still further increased by the liberal indulgence in alcohol which seems almost universal among men at the sea-shore—for those who are very abstemious at home seem to find in the salt air a something that increases or originates a desire for alcohol; and these great appetites are allowed unbridled indulgence in crabs and oysters and the like, until a severe colic calls a halt. Late hours are the rule among these transient visitors, and matutinal headaches are not unknown. When to excessive eating, drinking, and labor (for amusement), we add the improper methods of bathing, about which we write elsewhere, we can readily understand why these visitors of a week go home exhausted. The hops also furnish a source of danger. The rooms are hot, from the presence of hundreds of gaslights and of persons, and when a young man and his partner, heated above 100° F. by dancing, slip out to promenade on the piazza, subject to a strong wind, we can readily understand how a tendency to disease of some internal organs may be lighted into activity—for it is an ancient and erroneous superstition that one cannot "take cold" in salt air.

The "cottagers" lead a quieter life, and hence derive more benefit from the invigorating and life-giving atmosphere; but even this class participate more or less in the dissipations of sea-shore life. Of course, young folks go to the sea-shore "for fun," and they are going to have it, no matter how much we "old fogies" may preach against their methods. Still, this fact does not relieve us from the responsibility of pointing out what we consider hygienic errors in sea-shore life.

NOTES AND COMMENTS.

The Retention of Hair in the Axilla.

Evolutionists will be interested in reading the following remarks which Dr. A. Wyndham Martin publishes in the *Edinburgh Med. Jour.* for June, 1884:

The different views held on this subject render the question one of great interest to the student of science. The only reference to the subject made by Darwin, in the "Descent of Man," is the following:

"That the hair is chiefly retained in the male sex on the chest and face, and in both sexes at the junction of all four limbs with the trunk favors this inference—on the assumption that the hair was lost before man became erect, for the parts which now retain most hair would then have been most protected from the heat of the sun."*

Amongst many other theories held are the following:

1. That the hair in the arm-pit is intended to reduce the friction caused by the movements of the arm.

2. That at the age when the hair makes its appearance there is a greater supply of blood to the part.

3. That the increased heat serves to develop the hair follicles and sebaceous glands in greater abundance.

* Descent of Man, 2d edition, p. 57.

With regard to No. 1, any person on a slight examination of his own arm-pit will find that there is no friction at the part where the hair is most developed. As to 2, if due to an increased supply of blood to the axilla, it should also appear on the mammary region in the female—as there we see a much greater change in the blood-supply at the age of puberty. With regard to 3, the development of hair on the face in the male at about the same age is not generally attributed to an increase of heat and consequent development of hair follicles and sebaceous glands. If it be so in the axilla, why should the female lack hair on the face, considering that both sexes share in the possession of it more or less in the axilla? If we examine the subject morphologically instead of physiologically, we see that the axilla, the inner part of the fore limb, corresponds to the groin, the inner part of the hind limb. Now the presence of hair in the pubic region is sufficient, by the law of "correlation of growth," to account for the presence of hair in the corresponding part of the fore limb, the axilla. On examination it will be found to bear a fixed ratio to that of the pubes, and also to correspond closely in color. Sexual selection in primitive man, before he clothed himself, is sufficient to account for the hair on the pubes. The sexual passion in both sexes will be found to be in proportion to the development of the pubic hair, and the "law of inheritance" will explain its persistence.

A Peculiar Form of Pneumonia.

Before the Manchester Medical Society (April 16, 1884,) Dr. Dreschfeld read a paper on a peculiar form of pneumonia, which seems to have been very prevalent lately in Manchester, and which was especially interesting, as it resembled in its symptomatology the "epidemic pneumonia" described by several observers in recent times. The disease commenced, as a rule, without a rigor, its onset being marked by general malaise and pyrexia, which lasted for two or three days before any characteristic physical chest-symptoms appeared. When these appeared, they had a very distinct creeping character: they consisted of fine crepitations, with dullness on percussion, and commenced at the apex of one lung, gradually passing downwards to the base, and then often attacked the other lung in a similar way. The characteristic rusty sputum was absent in about half of the cases, where there was either no expectoration at all, or expectoration of a muco-purulent character. The temperature was never very high, and the curve irregular. In one case, where the invasion of each lobe was more sudden, every fresh attack was marked by a sudden rise of temperature. In but few cases was there a distinct crisis; where recovery took place the temperature showed a more gradual defervescence. The disease ran a somewhat protracted course, and was very fatal. Amongst its complications were noticed enlargement of the spleen, pericarditis, and albuminuria. Post mortem, the lungs showed typical croupous pneumonia, the several stages of which could often be seen in the same lung. Portions of the lung, placed at once in absolute alcohol, and examined after Gram's method, showed the presence of enormous masses of diplococci; these were seen both in the alveoli amongst the exudation, as well as in the lymphatics and capillaries. This form of pneumonia bore a very close resemblance to the pneumonia which occasionally occurred epidemically, as described by Costello, Jürgensen, Kühn, and others; it also resembled the pneumonia observed complicating typhoid fever and other zymotic diseases, and the pneumonia observed in old people and in alcoholics. It seemed to form a connecting link between the ordinary pneumonia and the so-called septic and the epidemic pneumonia. The inferences which Dr. Dreschfeld drew from his observations were these:

1. However much croupous pneumonia might vary in type and symptoms, there was only one kind of pneumonia.

2. The causes, such as catching cold, etc., were simply predisposing and not exciting causes.

3. Pneumonia was due most probably to a specific infective agent, the pneumonia-coccus.

Carbolic Treatment.

Before the Irish Academy of Medicine, (March 26, 1884) Dr. Cahill, in a paper on carbolic treatment, said that antisepticism was superfluous, as fermentation never occurred in the vital fluids, blood, pus, serum and lymph, until they died, and when once dead they should be removed. He traced an analogy between blood and pus, in that both died in the largest containing vessels first, and that dead substance introduced into either surrounded itself with a zone of dead material; for instance, dead bone in pus. He attempted to prove that air was a foreign body, by quoting the phenomena of canalization, and in other ways. He deprecated the system of classing a large number of drugs under the heading "antiseptics," and thought each substance should be regarded on its own

merits, alleging that, although antisepticism was useless, the carbolic treatment was highly valuable in wounds and sores of a strongly inflammatory tendency, as devitalizing or suspending vital processes in the tissue-elements. In support of this view, he instanced the effects of the spray on the hands of operators. Carbolism in preventing suppuration round sloughs (as adduced by Mr. Cheyne) was partly due to the same principle, and partly to that property of carbolic acid by which it promotes the absorbent powers of granulation-tissue. Mr. Thompson pointed out that Lister was by no means confined to the use of carbolic acid in his treatment, but used perchloride of mercury, eucalyptus, thymol, etc. He dissented from Dr. Cahill's conclusions, and said that Lister's system had the effect of reducing the death-rate and practically wiping out in surgical practice pyæmia and septicæmia.—Mr. W. Thornley Stoker thought Dr. Cahill's point was to give a new explanation of the way in which the effects ascribed to Lister were produced.—Dr. Cahill said he did not attack carbolic acid, but Listerism—carbolic acid being, in proper cases, a very valuable drug. He quarrelled with Lister for using it indiscriminately in all cases, and thought Lister had done a great deal of harm by introducing antiseptic surgery. No doubt Lister used thymol, eucalyptus, etc., but he had gone back to carbolic acid, as mentioned in Cheyne's *Surgery*, which, according to Lister, himself, was the best source of information as to his system.

Case of Diphtheria Treated by Tracheotomy, Peptonized Enemata and Iodoform.

Dr. R. Shingleton Smith reports this case in the *British Medico-Chirurgical Journal*, March 1, 1884:

Florence H., æt. 6, admitted December 26, 1883, in state of asphyxia, with abundant exudation visible in throat. Tracheotomy was performed immediately, and gave marked and immediate relief.

December 27. Temperature was 102°, urine had one-eighth albumen, and there was much swelling of cervical glands.

December 30. The edges of the wound were gaping, stitches had sloughed out, and glands very much swollen.

December 31. Milk taken in by mouth at once came out through the tracheal tube and gave rise to much choking cough. Nutrient enemata of peptonized milk, and Slinger's capsules, were given; all food by the mouth discontinued.

January 4. The child was wasting rapidly, although the temperature was normal, and threatened pneumonia had cleared up. The enemata not being well retained, peptonized milk was injected into the stomach through an œsophageal tube, but was only partially retained. The tube in trachea was then removed; the sloughing of wound had ceased, the swelling of glands subsided. In a few days the child could swallow solid food, although liquids would still pass down the larynx. The wound in the neck gradually healed, the opening in trachea closed, power of deglutition both of solids and liquids returned. The child rapidly improved in strength; speech returned in about a month, and the urine was free from albumen six weeks after admission.

The only essential element of treatment, other than by tracheotomy, peptonized enemata and œsophageal injections, was iodoform. This was given in grain-doses with mucilage every four hours during the first five days, till the power to swallow was lost. Iodoform was also painted on the fauces, and diffused in vapor throughout the air of the steam-bed. It was also applied to the wound and over the tube in the form of iodoform wool.

Bronchial Gangrene from a Foreign Body.

The *Wien. Med. Blätter*, of January 24 and 31, describes a case of bronchial gangrene occasioned by the inspiration of a small piece of bone. The patient was a strong man, aged thirty-seven, who came to Dr. Mader's clinic in Vienna on December 20, 1883, with the history that on November 15, as he was eating some soup, he swallowed a piece of bone, which stuck in his throat. This caused so much dyspnœa, that he was obliged to spend the night sitting up in a chair. Next morning he saw a medical man. who used a bougie, and relieved him from the sensation of the presence of a foreign body. He rested from work for four or five days, but soon afterwards he was seized with rigors, pain in the right side, and severe cough, apparently from having caught cold in a cellar. On admission, he had a certain amount of fever, and the respiration was hurried, but there was no sinking-in of the jugular regions. There was dullness on percussion over the right side, with some tenderness posteriorly, over the region of which no breath-sounds could be heard, the respiration elsewhere being vesicular. The sputa were not fœtid, but the patient remembered that the mucus he spat up three days after the accident had a bad smell. Fœtor appeared in the course of the three days following his admission, as the cough grew more severe, and the case went

on, with increasing fever and fœtid expectoration, until January 5, when it ended fatally, with symptoms of suffocation. At the necropsy, the lower division of the right bronchus was found completely stopped up by a piece of bone; putrid bronchitis was found on both sides, and lobular pneumonia in the left lower lobe. A small solution of continuity was found on the posterior wall of the larynx, on a level with the arytenoid cartilage, showing that the piece of bone must have stuck there in the first place; and a similar lesion at the bifurcation of the trachea pointed to a second stoppage of the foreign body, before it slipped finally into the right bronchus, where it was found. The case contains a caution from a clinical point of view, as the use of the laryngoscope, indicated by the dyspnœa, might have shown the true nature of the case at the beginning.

A Case of Floating Liver.

Dr. J. B. Arini describes an interesting case of floating liver in a recent number of the *Anales del Cerculo Medico Argentino*. The patient was a young married lady, in whom the abdominal muscles were weak and flaccid after child-bearing. Wishing to put on a new dress which was found to be too tight, she, with the aid of another person, forcibly squeezed herself into it by lacing her stays extremely tight. Thus compressed, she started for church, but, before arriving there, was suddenly seized with an internal pain and sensation of tearing, which caused her to faint. Symptoms of peritonitis followed, obliging her to remain in bed for some time. On the subsidence of the peritonitis, a large swelling was noticed in the middle and right side of the abdomen. This tumor, which was movable, caused her great pain on walking, and she could only sleep on the right side. Dr. Arini first saw her eighteen months after the accident; he then verified the presence of a tumor, presenting the character of the liver. The anterior surface was smooth and convex, and not painful to gentle pressure; its lower border was sharp with a notch, its upper border thick and smooth; the tumor was movable, and could be raised upwards and to the right under the false ribs; the normal dull zone in the right hypochondriac had given place to a clear tympanitic sound. The periodical changes observed in the tumor coinciding with digestion, its movability, the subjective phenomena of weight and traction, and the physical signs, added to the history of sudden onset, recent confinement, and pendulous abdomen, all made the diagnosis clear. The treatment consisted in the employment of a species of support or corset, with a concave metal plate well padded, on which the thin border of the liver rested; the organ by this means was held up more or less in its normal position. The patient found great relief from this support, and was able to walk and to lie on the left side without difficulty.

An Important Point in Testing for Albumen.

It is customary for the physician to request his patient to send him a sample of urine passed the first thing in the morning, when he desires to examine it for albumen. That this may mislead him is suggested by the following case, which a correspondent reports in the *British Medical Journal*, July 5, 1884:

A girl, aged 13, fairly healthy, but not over strong, was brought to him about ten months ago, said to be suffering from "incontinence of urine" and debility. On examining the urine, he found that it was loaded with albumen; there was no anasarca, and no cardiac mischief. He prescribed tincture of perchloride of iron and dilute nitro-hydrochloric acid, with the result that nearly all trace of albumen had disappeared in about six weeks, when she went to the seaside, and he lost sight of her for about two months. Soon after her return he again examined the urine, and found it loaded with albumen. He again prescribed the iron and acid, and gave directions that the urine first passed in the morning should be sent to him for examination regularly every few days. This was done, and he was glad to find almost immediately marked improvement, until one day, by mistake, urine voided in the middle of the day was sent, and this he found to be loaded with albumen. He then gave directions that two samples should be sent on the same day every week, one being that passed the first thing in the morning, and the other later in the day. The result of his investigation was, that the former was perfectly normal and free from albumen, and the latter was decidedly albuminous. The amount of albumen varied, sometimes being considerable, sometimes hardly perceptible. At the present time the morning urine is perfectly free, but that passed at midday contains a decided trace, and this state of things has existed for some weeks past.

Peritonitis in an Infant.

To the New York Pathological Society (April 9, 1884), Dr. J. Lewis Smith reported this case. He had seen the patient only the day before its death, which occurred on the fourteenth day after

birth, in which there had been nothing unusual. A week before his visit the nurse said the child had been very fretful. An increase in the temperature was afterward noted. He found evidence of peritonitis. There was great distension of the abdomen, with meteorism; the child cried when pressure was made over the abdomen. The rectal temperature was 102.4° F. During the first ten days of life the child had only gained one ounce in weight. Some matter could be squeezed from the umbilicus. The cord had separated at the seventh day. The autopsy was made by Dr. Welch. The most marked lesions were found along the course of the umbilical cord, where fibrinous pus was quite thick. The lymphatic vessels along the lower surface of the diaphragm were also filled with pus, and Dr. Welch had stated that there probably would have been an extension of the inflammatory process to the pleura had the child lived longer. The umbilical vein was filled with grayish-red, broken-down, and purulent thrombi, closely adherent to the walls of the vessel. Dr. Welch explained the peritonitis by the statement that micrococci, which were present, had found their way through the umbilical vein into the peritoneal cavity, and this fact also explained the reason for there having been a greater degree of inflammation along the course of the vein. Dr. Smith said that if this explanation of peritonitis in these little patients was accepted by pathologists, it was interesting and suggestive. Some weeks ago there had been some puerperal fever and erysipelas in the maternity wards of the institution where the child died, and for that reason the wards were closed for a time. Whether the present case was in any way connected therewith, he was unable to say.

Idiopathic Purulent Peritonitis.

Prof. Leyden has recently described (*Deutsche Med. Wochenschrift*, April 24,) three cases of idiopathic peritonitis. One of these, in a male, ended in recovery, so that its precise diagnosis remains uncertain. The other two were in females, aged twenty and twenty-seven years respectively, and the peritonitis, which was purulent, ran a rapidly fatal course. It had no connection with menstruation, and the post-mortem examinations showed the absence of any local primary inflammation of the pelvic or abdominal organs. In one of these cases the interesting discovery was made of an abundance of micrococci in the exudation, as well as in the deeper layers of the abdominal wall and the diaphragm. They resembled the micro-organisms which have been met with in puerperal peritonitis and other purulent exudations — e. g., pleurisy. The origin of such cases is veiled in obscurity; but perhaps, as Leyden thinks, the detection of these micro-organisms may lead to an explanation, which at the best must be hypothetical—viz., that in intestinal or menstrual derangements such organisms may gain access to the peritoneal cavity and excite inflammation. He speaks somewhat despairingly of treatment, including mercurial inunction, and says that it has long been a question with him whether such cases ought not to be dealt with surgically, on the same principles that an empyema is treated. The difficulty of establishing a diagnosis of the nature of the peritoneal effusion in these very acute cases forms perhaps the main hindrance to the adoption of a measure which might often be the sole means of saving life.

Catheters and Self-Catheterism.

While much more common in England, yet, the custom of *self-catheterism* is becoming more usual in this country. And as gum catheters (the kind most in use) become very sticky, increase in bulk and deteriorate in quality, becoming very liable to break off in the urethra, it is with much satisfaction that we note that Dr. J. B. Mitchell states in the *Medical Press*, June 25, 1884, that a catheter that has been smeared inside and outside with oil, when exposed for an hour or two to the action of pyroxylic ether, is as clean and smooth as it was before use. He also suggests a most excellent method of using oil for lubricating purposes. When a certain quantity of castor oil is, by exhaustion at the superior orifice of the catheter, sucked into the tube of the instrument, it does not at once seek to escape, but keeps its place till the constricted part of the urethra is reached. The catheter, with its internal as well as external charge of lubricant, having arrived at the point where resistance has to be overcome, pressure of a stripping character exerted between the finger and thumb, in a downward or inward direction, upon the extruding upper end of the instrument, by expelling the oil wherewith its opposite end is charged, floods the urethra with the lubricant at the constricted part, and bears along, as it were, the catheter point through the prostatic rapids, landing it safely in the bladder. Experience has abundantly shown that the flooding, when copious, is always completely effectual in the shooting of the urethral narrows.

Cleansing the Uterus after Abortion.

Dr. David Inglis publishes a paper on this sub-

ject in the *Am. Jour. Obstetrics*, April, 1884, in the course of which he says:

"My experience with intra-uterine injertions in the cases under consideration has been markedly and uniformly favorable. By the use of the double tube, the danger of any of the injected fluid being forced up the Fallopian tube is practically none. The effect of disinfectant injections in reducing temperature in cases where constitutional disturbance had already set in, has been unequivocal. In one case in which I was called to a patient in whom a portion of placenta retained had caused a temperature of 105.5°, the drop to 99° within three hours after thorough disinfection of the uterine cavity gave most distinct evidence of the efficacy of the treatment. While I have never as yet had any untoward effects from the use of intra-uterine injections, it is right to add that it would seem that their use long (six or seven days) continued after confinement tends to increase the danger of late post-partum hemorrhage.

In conclusion, I would specially call attention to flexion of the uterus as a cause of retention of the lochial discharge, and thus of certain cases of puerperal fever. The mention of it at once suggests the reasonableness of prompt reposition and thorough cleansing.

Low Temperature in Pneumonia.

Before a recent meeting of the New York Clinical Society, Dr. Janeway called attention to the significance of low temperatures in pneumonia. He had recently seen three cases, two of which proved fatal, and the third, which was still under observation, would probably result in the same way. The first case was that of a woman, fifty-five years of age, whom he had seen on the sixth day of the disease, hæmoptysis having given rise to the suspicion of phthisis. He found well-marked consolidation at the base of one lung, and some signs on the other side. The rectal temperature was only 100° F. The patient died on the ninth day. In the second case he saw the patient on the fourth day, and there had been no marked elevation of temperature. Here, also, the physical signs were plain. In the third case, the highest temperature noted thus far has been 102°. Such cases used to be called asthenic pneumonia. For several days before taking to bed, the patients were often sick without any marked rational symptoms, or the symptoms might be misleading, like the hæmoptysis in one of the cases he had referred to; and yet they might die a day or two later. He thought this low temperature a bad symptom, although he had seen it followed by recovery. In the cases referred to, the pulse had been rapid—in the first one from 150 to 160, in the second from 120 to 130. He also called attention to the fact that apex pneumonias were often overlooked, because the physician examined only in front, and the signs were not usually to be found there, but high in the axilla and behind. The percussion-note in front was often vesiculo-tympanitic from imprisoned air. Many such cases were diagnosticated as remittent fever.

Imperforate Hymen Opened without Antiseptic Precautions.

Dr. M. G. Biggs reports this case in the *Brit. Med. Jour.*, May 10, 1884:

"E. S., aged 16, a servant, had never menstruated, although she was a well-formed girl. She had, however, suffered from pain at distinct intervals, and, when she sent for me, her mother said she had been in severe pain all the previous night, and was then so bad that she was rolling on the bed, and that the womb had come down externally. On examination there was a distinct bluish projecting membrane, with marked fluctuation; the only opening to be found was that of the urethra. A triangular piece was removed from the centre of the membrane, and there was an immediate rush of a considerable quantity of dark-colored discharge, with instant relief from the pain, which did not recur. When the discharge had ceased, the parts were covered with a piece of linen rag soaked in carbolic acid lotion (1 in 40), and this was ordered to be continued; but, as often happens in this class, the mother was somewhat careless, the rag was allowed to dry or to fall off, so that we may fairly say that there was a free access of non-carbolized air. She was kept in bed during the remainder of that day and the next, but there was no rise of temperature, and then she was allowed to get up and resume her work, which she did without any bad effects."

The Therapeutics of "Horizontal Position."

Dr. R. H. Gunning, of Edinburgh, tells us that it is enough to look at the veins on the back of the hand or inside of the leg, to see the effects of hydrostatic pressure. The limbs being perpendicular, the veins swell; placed horizontally, they become again normal. If so in the limbs where the veins have valves, more so in the veins where there are no valves, as in the lower intestine and in the reproductive parts. How easy to prevent varix, varicocele, piles, and leucorrhœa, by re-

clining sufficiently ; or to develop them by overstanding or over-walking. This is what he thinks is not sufficiently estimated in books nor in practice. Too much is expected from local applications or operations of one kind or another, and too little is trusted to the help of position, or physical law.

Then we must not forget that the force of the heart and general circulation is also diminished by the recumbent position. The pulse increases in frequency by sitting up, and more by standing up.

Septicæmia Accompanying Lacerated Cervix.

Dr. William W. Seymour contributes a paper on this subject to the *Am. Jour. of Obstetrics*, April, 1884, which is thus summarized :

1. Until the cervix is fully dilated, the presenting part must be kept back and the cervix supported to prevent its laceration by the presenting part or the after-coming shoulders.*

2. Hot water injections will, immediately after delivery, make lacerations of cervix and vagina patent which otherwise would not be discovered by the touch for several days.

3. In every case of suspected cervical laceration, a careful search should be made with the uterine sound for supra-vaginal cervical lacerations.

4. Large doses of quinine, twenty or so minutes prior to the uterine injection, will prevent chill and probably also uterine colic.

5. A supra-vaginal laceration of the cervix should be treated by the armed probe and irrigation.

6. Examination within the first few days after labor would probably show a fair percentage of peri-uterine hematomata from laceration.

Uræmic Amaurosis.

Dr. A. Friedenwald thus summarizes a paper on this subject in the *Med. News*, August 9, 1884:

1. That when amaurosis suddenly overwhelms a patient in both eyes with no ophthalmoscopic change, uræmia should be suspected even in the absence of any other prominent uræmic symptom.

2. That uræmic amaurosis will continue only as long as the uræmia exists, and will disappear when the function of the kidney is re-established. When permanent injury to sight is observed, it may be due to pre-existing retinal changes, not at all uncommon in Bright's disease.

3. That the chances for a full return of sight are somewhat impaired when the patient has been the subject of recurring attacks.

4. That by exhibiting jaborandi and other means for inducing free diaphoresis and by free purgation a catastrophe may be averted in the general forms of uræmia, but when it occurs in pregnancy, premature labor is the only remedy which promises safety to the patient.

*Probably, apart from instrumental cases, the worst cases of laceration of perineum or cervix are produced by the shoulders.

Ammonia as a Prophylactic Against Cholera.

Dr. S. W. Ingraham, of Chicago, writes to the *Med. Record:* "During the years 1865 and 1866 I spent much of my time in New York city, and as the cholera was quite epidemic there during those two years, I took occasion to ascertain what class of people were least subject to it. I found that the men who worked in horse stables were rarely, if ever, attacked with the disease, and that their families were less liable to the contagion than persons of other occupations living in the same localities, with the endemic influences nearly or quite equal. Upon special examination I found the clothes and even the skin saturated with ammonia to such an extent that when they came in close proximity to me I could plainly discern its odoriferous properties. From this I was led to believe that their whole bodies were more or less under the influence of the ammonia, and that the cholera contagion would not attach to them."

News and Miscellany.

Sad Suicide of a Medical Man.

An inquest was lately held at Northwich, in Cheshire, England, on the body of Dr. Cadwallader Brooke Wolseley, a cousin of General Lord Wolseley, who committed suicide by taking a large dose of hydrocyanic acid. The deceased was in practice in Northwich, where he was greatly respected by the inhabitants, and had been engaged in seeing and prescribing for patients up to within an hour previous to the commission of the fatal act. No evidence was forthcoming at the inquiry to indicate any sort of cause for the occurrence, but one witness desired to explain that deceased had been subject to pains in the head, and had suffered from a slight sunstroke some years ago. Strangely enough, however, the coroner, Mr. H. Churton, decided that this evidence could not be entertained; why, he does not appear to have said. To ordinary understandings it would have been of essential service in helping to elucidate the circumstances of the case, and it might have been more generally satisfactory had the testimony been admitted. The verdict ultimately recorded was to the effect that death was caused by taking prussic acid, and that deceased was laboring under temporary insanity at the time.

British Medical Association.

The fifty-second annual meeting of this Association was held in Belfast, Ireland, July 29, 30 and 31, and August 1, 1884.

The president's address was delivered by Dr. James Cuming. The address in Medicine, by Dr. William M. Ord. The address in Physiology, by Dr. Peter Redfern. The address in Obstetric Medicine, by Dr. George H. Kidd. "Old and New Views in Medical Science," by Dr. James W. T. Smith. "Gastrostomy; Radical Cure of Hernia; and Thyroidectomy," by Sir William MacCormac. "The Surgical Aspects of Obstetrics and Gynecology," by Dr. Clement Godson. "The Cholera Microbe, and How to Meet It," by Dr. Charles Cameron. "The Treatment of Immature Cataract," by Dr. W. A. McKeown. "The Pathology of Insanity," by Dr. George Henry Savage. "The Relations of Physiology and Pathology," by Dr. W. S. Greenfield. "On Methods of Therapeutic Research," by Dr. T. J. Maclagan. "On the Nosological Relations of Chronic Rheumatic (Rheumatoid) Arthritis," by Dr. Dyce Duckworth. These are the principal papers so far reported. We will from time to time present abstracts of them.

Hydro-Therapeutics at Saratoga.

The *N. Y. Med. Jour.* says that in spite of the popularity of some of our American watering-places, and the vague trustfulness with which patients with chronic ailments resort to them, it must be said that, in comparison with those of other countries, our resources in the shape of mineral springs have not hitherto been turned to account therapeutically in any way deserving to be called systematic or intelligent. It is undoubtedly true that in certain parts of Europe the powers of mineral waters are magnified far beyond their real worth, and the indications for their therapeutical employment over-refined; but it is very certain that we have erred in the opposite direction. It is on all accounts to be desired that a systematic study should be made of those of our waters that have been conceded to have any just pretension to definite medicinal properties, and we are glad to learn, therefore, that one of the resident physicians of Saratoga, Dr. R. C. McEwen, is about to enter upon the study of the Hathorn spring, somewhat after the manner of the bath physicians of Europe.

The Plague on the Turco-Persian Frontier.

The Berlin correspondent of the *British Med. Jour.* (July 26, 1884), writes: "About the middle of June a telegram reached Berlin announcing the outbreak of bubonic plague in the neighborhood of Bagdad. Some days ago, news reached Berlin, from St. Petersburg, that, in consequence of the outbreak of a malignant epidemic on the Turco-Persian frontier in Kerbala and the neighborhood, the Persian government had drawn a strict *cordon* to prevent the plague from spreading. The governor of Baku has refused to grant passports to pilgrims wishing to go to Kerbala, in order to prevent the epidemic being brought to the Caucasus. The nature of the epidemic is not announced." This is probably the same plague that was spoken of in June. News has also reached Berlin, from St. Petersburg, that the Siberian plague is now raging in the government of Pleskoff, and that several deaths have already occurred. It is, moreover, asserted that the authorities are not taking proper measures against the plague.

The Late Mr. Hawkins.

Speaking of the late Mr. Cæsar Hawkins, Sergeant-Surgeon to the Queen of England, the *London Med. Times* says:

"Like the majority of those who have attained high rank in the profession of medicine, Mr. Hawkins was a man of character as well as ability. One who knew him for nearly fifty years writes of him: 'During all these years he was ever the same—most industrious and painstaking in all matters relating to his work—high-minded and honorable in all that was connected with the interests of his profession—kind and liberal to a degree, that truly it may be said, his right hand knew not what his left gave away. All who had the privilege of his friendship will endorse this estimate of his character. He was one of the most accurate and clear-headed of men that I had ever anything to do with—no lover of ostentation—no seeker after personal advancement by show or talk—but true in every sense of the word, and a thorough high-minded gentleman.'"

A Point in Abating Nuisances.

The right of courts to abate nuisances is an undoubted one, but great care is exercised lest injustice may be done by the hasty exercise of this power. A good illustration of the extent to which courts will go in this direction is shown in a recent English case, where a railroad company had established cattle-yards in a place where they soon became a great nuisance and offensive to health. The company was allowed by law to establish such cattle-yards, but the act of Parliament said nothing as to what should be done in case they became a nuisance. Upon a motion to enjoin the railroad company from continuing the yards, the company did not in answer show that the location chosen was the only place where cattle-yards could be placed; and as this was not done, an injunction was directed to issue.

The Berlin Physicians and Cholera.

The Berlin Clinical Society (Verein für innere Medicin) at the meeting on the 14th of July, discussed the subject of cholera. Dr. S. Guttmann opened the debate, and recommended the formation of a committee to collect and report upon the relative value of various therapeutic measures, and consider what influence the discovery of the cholera bacillus should have in the adoption of prophylactic and curative methods. An animated discussion followed, and a committee was nominated consisting of Drs. Leyden, Fräntzel, Klaatsch, Reiss, Goltdammer, Lehnert, Baer, Wernich, P. and S. Guttmann, and Guttstadt. Dr. P. Guttmann stated that accommodation for 500 cholera patients could be provided in the city hospital at Moabit. At the commencement of the sitting, Dr. Kronecker exhibited a newly-devised apparatus for saline transfusion.

Medicine in Syria.

Dr. George E. Post, a medical missionary connected with the Presbyterian Church of this country, who is living at Beirut, Syria, has acquired a great reputation among the Turkish officials for his skill in surgery, and could easily acquire a large income if he were to receive pay for his services. He devotes, however, his entire time to the poor, and the calls upon him are immense in number and in variety. He has prepared a series of text-books in Arabic on surgery, materia medica, botany, zoölogy, and physiology, and edits a monthly medical journal. He is at present employed on a work descriptive of the flora of Syria and Palestine, the first work of the kind on the subject in any language.

Milk vs. Stimulants.

"The greater my experience becomes," writes Dr. Clauston on Annual Raport of the Royal Edinburgh Asylum for the Insane, "I tend more to substitute milk for stimulants. In very acute cases, both of depression and of maniacal exaltation, when the disordered working of the brain tends rapidly to exhaust the strength, I rely more and more on milk and eggs made into liquid custards. One such case this year got eight pints of milk and sixteen eggs daily for three months, and recovered under this treatment. I question if he would have done so under any other. He was almost dead on admission, acutely delirious, absolutely sleepless, and very nearly pulseless."

Items.

—Mr. Cæsar Hawkins, Sergeant-Surgeon to the Queen of England, died July 20, aged 86 years.

—Dr. P. M. Wise has been appointed Superintendent of the Willard Insane Asylum, in place of Dr. Chapin.

—Another fatal accident has occurred in the Alps, the victim being a medical student, son of Professor Bamberger, of Vienna.

—The American Academy of Medicine will hold its annual meeting at Baltimore, Maryland, on Tuesday and Wednesday, October 28th and 29th, 1884.

—M. Paul Bert has proposed in the French Chamber a law which compels every doctor to report without delay the appearance of a case of cholera.

—M. Closmadeuc has recently performed the Cæsarian operation successfully both for mother and child. This makes his third operation and third success.

—The University of Heidelberg is about to celebrate its five hundredth anniversary. The Baden Parliament has voted $40,000 to meet the expenses of the occasion.

—In the *Edinburgh Med. Jour.*, Aug., 1884, Dr. A. D. Leith Napier reports a fibrinous polypoid uterine tumor, with secondary hemorrhages, and removal of tumor.

—The Academy of Medicine of Paris has, on the report of Dr. Brouardel, unanimously voted that quarantine on land is impracticable in France, and that the process of disinfection at present imposed upon travelers and their luggage is inefficacious.

—The Trustees of Jefferson Medical College have had placed in their hands the resignation, by Prof. Robert E. Rogers, of the Chair of Chemistry in that school.

—"Congestion of the right kidney" is the diagnosis made by his attending physician of an indisposition from which Rev. Henry Ward Beecher has been suffering.

—Prof. Aeby, of Berne, has been appointed to the Anatomical Chair of the German Medical Faculty of the University of Prague, and Prof. Strasser is named as his successor at Berne.

—The French government has conferred the Order of the Legion of Honor upon Prof. Koch, in recognition of his services in connection with the investigation into the causes of the outbreak of cholera.

—The National Board of Health held an annual meeting in Washington, Wednesday, July 30, and elected the following officers:

President—Dr. James L. Cabell, Virginia.

Vice-President—Dr. Stephen Smith, New York.

Secretary—George E. Waring, Esq., Rhode Island.

—The executive committee of the commission appointed at the recent session of the Legislature to investigate the sanitary condition of the tenement houses of New York, commenced the work of inspection during the last week of July. It consists of Drs. Moreau Morris and Abbot Hodgeman, Charles F. Wingate, Sanitary Engineer, and William P. Esterbrook, Superintendent of Buildings.

—One of the comic papers has this paragraph: "A patent medicine manufacturer died in New York last week. Before he died, his friends asked him how he would like to be buried. He had just strength left to say: 'Insert me top column, next to reading matter, 52 times, electro by mail,' and then he closed his eyes and passed away to that bourne where there are no omissions nor wrong insertions."

—The English Parliament has refused to pass the bill forbidding pigeon-shooting matches, although the *London World* says: "It was abundantly proved in the course of the debate that pigeon-shooting entails the systematic practice of the most execrable cruelties. The physical injuries done to the birds in order that they may baffle the marksmen, or that they may be more difficult to hit, are of the most hideous description."

—At the suggestion of Dr. Cyrus Edson, of the New York Health Department, an ordinance has been passed forbidding the use of vessels made of brass, lead, copper, or other metallic substance in the sale of beer, soda-water, syrups, and other beverages or flavoring materials, on account of the danger of the formation of compounds detrimental to health. An investigation into the character of the lining of the soda-water fountains of Brooklyn is at present being made by Health Commissioner Raymond.

DEATHS.

FLEMING.—August 9, 1884, at the residence of his parents, Dr. W. and E. J. Fleming, Port Byron, Ill., Charles S. Fleming, aged 17 years, 1 month, and 20 days, of cerebral disease.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

IS FRIGHT AN ESSENTIAL PATHOGENIC ELEMENT IN CHOREA?

BY J. C. BIDDLE, M. D.,

Surgeon-in-Chief to the State Hospital for Miners, Ashland, Pa.

It has been contended that sudden fright is the main causing element of chorea. It has even been said that young children under eighteen months never suffer from this disease, because they cannot be frightened; not knowing a danger, it is impossible to make such an impression on their central nervous system as to produce a malady, so generally induced by a sudden fright, as chorea. Before debating the subject, I wish to report the following case:

David T., æt. 14, a strong, physically well-developed boy, was admitted to the State Hospital for Miners, March 25, 1884, for injuries to his left arm and foot. He and his mates were playing marbles near by the railroad. David happened to be the winner, and to get away, so that his playmates would not rob him of his booty, the thought struck him, to jump on a coal train just then passing. He mounted all right, but in jumping off his hand became fastened in the handle of the car, and he was dragged along for a distance of about fifty yards, when his hand suddenly becoming disengaged, he fell with his left arm and foot under the wheels. He scarcely as yet knew what had happened, and he tried to rise and to stand on his feet, when he discovered his left arm hanging loosely by his side. At the same time the left foot gave way under him; he felt a severe pain, a sickening sensation came over him, and he dropped down. His arm was lacerated and pulpified from the wrist to above the middle of the upper arm. He was taken up and carried to his home, where his arm was bandaged, and his foot stitched nicely enough, making it appear as if he had received a simple cut. But high fever and swelling setting in, and the boy complaining of excruciating pains, he being an orphan, and his friends fearing he could not receive the proper treatment there, about five hours after the accident decided to send him to the hospital under my charge.

At once convinced of the impossibility of saving the arm, which for the distance mentioned really was but a crushed mass, in fifteen minutes after the boy's admission I amputated the injured arm in its upper fourth. On account of a rent in the skin on the anterior part of the arm extending well up on the coraco-brachialis muscle, I made two lateral flaps. Every experienced surgeon knows, that in cases of injury flaps cannot always be formed in the exact manner systematic writers on surgery teach us; we have to cut the flaps to suit each individual case. By following my usual principle, to adapt the operation to the case, I am satisfied that I saved the boy fully two inches of bone, with plenty of muscle to cover the bone, and with skin enough to protect the muscle.

Twenty-four hours after the accident his toes on the injured foot turned a livid hue, plainly indicating the serious damage, which the circulation had received. I applied emollient poultices with hot water-baths every three hours. Seventy-two hours afterwards the line of demarcation had formed just above the ankle-joint, and I decided

to remove the now dead foot just below the middle of the leg, employing the circular method. The boy's temperature, which had hitherto remained stationary at 102°, with a slight decline in the mornings, a few hours after the amputation of the leg, fell to 99°.

Although, as mentioned, the boy was strong and of muscular build, I put him from the beginning on a tonic treatment, knowing from experience that the general nutrition of such people in our neighborhood is not favorable to the development of a strong vitality. Besides, I had the first day the suspicion that amputation of the foot would become necessary, and to guard early the boy's system against the shock, which it would have to sustain in the case of two amputations, I resolved to use every effort to keep up the patient's vitality. I put him, therefore, from the commencement, on the bisulphate of quinia and the tincture of the chloride of iron, while his diet consisted of beef tea and milk, alternating at regular intervals. Locally to the stumps I applied a solution of carbolic acid, glycerin and alcohol, which in my hands has met with a better result than the $\frac{1}{1000}$ solution of corrosive sublimate. Whether it is the addition of alcohol or the effect of the carbolic acid, I will not venture to say; but with the local application mentioned I always succeed in obtaining quicker a healthy granulation, and oftener a *prima intentio*, than by any other method.

The arm healed by first intention, the ligature from the brachial artery coming away by the tenth day. The anterior portion of the flap on the leg sloughed away, but by gentle extension, caused with adhesive strips and a one-pound weight, I managed to have both bones entirely covered by a granulating surface.

The patient's temperature was taken by Mr. Jackson, the head nurse, daily at 8 a. m. and at 7:30 p. m., and a careful record kept of the same, from which I glean, that the temperature throughout was normal, with the exception of a few times, when it fell as low as 97⅘°. The pulse varied from 85 to 95.

Thus far the case had progressed very favorably, when on the fourteenth day I noticed peculiar twitchings and other irregular motions and muscular contractions in his right arm and right leg. Within a few days these movements became so violent that he was unable even to drink from a cup. I prescribed five drops of Fowler's solution, to be taken in water three times daily immediately after meals, daily increasing the dose by one drop. The arsenite of potash was continued until the symptoms of physiological poisoning—œdema of the eyelids—showed themselves. Otherwise the patient bore the medicine well; at least no disturbance occurred in the alimentary canal; but the boy became thin and exhausted, his sleep was restless, and he suffered from profuse perspiration. Notwithstanding these symptoms, I continued the treatment, but in diminished doses, for a period of five weeks, when the chorea had totally disappeared. The patient now rapidly improved and gained in flesh so that he was soon afterwards placed into the convalescent ward.

This is the history of the case, to which I will only add, that at the time the boy was suffering from the chorea, my friend, Prof. H. Engel, of Philadelphia, then on a visit to me, also saw him and coincided in my views of the case. We both minutely examined the boy to discover, whether he had been frightened at the time of the injury. He told the following tale:

He had been stealing a ride hundreds of times. Working in the mines, he had to be there at the exact time or lose a portion of his wages. He did not live far from the mine in which he worked, but then he had to walk a distance long enough to prevent him from playing longer than ten minutes. Accidentally a coal train passed, at the time for David to be at the mine, by the place where he generally played, and as the train also ran past the mine, the boy could afford to lose nearly a quarter of an hour more with playing by stealing a ride, the train carrying him so much more rapidly to his post of duty. As he had done so with immunity so many times, he never thought of the possibility of an accident, when he jumped upon the train. The handle of a car consists simply of an iron rod, so bent that a person can easily catch hold of it, and with plenty of room on top to pass a hand through. But towards its lower end this space becomes narrower and narrower, until for a distance of an inch or two the handle touches the wood. By some accident David got his hand into this narrow space, and when he jumped off he found his hand had caught in the handle. But even then he had no idea of danger. He simply made an effort to disengage his hand, not at all from fear of meeting with an accident, but because he did not care to be carried any further, as he had reached his destination.

While thus endeavoring to get his hand out of the handle, the hand suddenly became free, and ere he was aware of it, he was run over. As for the moment he did not feel the slightest pain—

the parts having been crushed—he was even then not frightened; but finding his left arm hanging down, he supported it with his right hand and stood up—probably first stepping on his right foot, as he would otherwise have never been able to raise himself. As soon as he stood upright, he also brought down his left—the injured foot—and it was then he was overcome by pain and a sickening sensation, and fell down. Up to that time he had not known that he was injured, and at no time, from the moment of his jumping on the cars till he again rose on his feet, had he been frightened, and for this simple reason, that he was not at all aware of any danger.

I have so long dwelt upon this point, because I wanted to prove that the fright had by no means caused the chorea. Besides, there are other weighty reasons against it. One is the long interval of time intervening between the appearance of the first symptoms of the nervous disease—two weeks—and the time of the accident. From the works of Keen, Mitchell, and Moorehouse, we glean that it is a common occcurrence to see nervous symptoms develop themselves several weeks after a severe injury. We also know the same fact of tetanus, which often makes its appearance in the third and fourth week after an injury. Usually, however, when chorea follows a fright, scarcely twenty-four hours, though sometimes a few days, intervene till the outbreak of the nervous disease; but to my knowledge, there is no case on record where, if the chorea was due to a fright, the first indication of it had appeared two weeks later.

In David's case the disease can neither have primarily been caused by the shock, first, because according to the history, there never was any perceptible shock, and even taken for granted there had been, any disturbance directly produced by a shock, will evince itself sooner, and not wait fully two weeks.

The only probable explanation is, that one or more nerves were irritated by the laceration of the tissues, and that this irritation (inflammation?) traveled up to the brain and was in some way carried or reflected in the usual manner to the opposite side. The length of time intervening speaks in favor of this assumption. It is possible that in traumatic tetanus a similar morbid process takes place, simply varying in degree. In both we have contractions independent of the will. How difficult it is to prove the existence of an ascending neuritis, has been shown by the laborious work of Dubler.*

Until such cases are examined with the same care, we will not arrive at a definite conclusion.

Many cases have been reported where a blow or a wound of a nerve or an irritation of peripheral portions of the nervous system induced chorea.* But in most cases the majority of authors still ascribe the disease to the fright or to the shock accompanying the injury, or they speak vaguely of an irritation of a nerve. It is to be regretted that the time intervening between the outbreak of the disease and the injury is so rarely mentioned.

Hughlings Jackson† believes that embolism of one corpus striatum leads to one-sided chorea. Though there is scarcely a probability that such was the case with David T., his peculiar restlessness and the loss of flesh coincided with the same symptoms, that Dr. Turkwell‡ fully believes in chorea to be due to embolism. To be sure, there was some disturbance in the healing of the stump of the left leg, sufficient to cause embolism; but the most careful ophthalmoscopic examination failed to reveal any disturbance of the circulation at the fundus of the eye. In case of embolism, the symptoms ought to have been more sudden; here the disease gradually developed itself and increased daily in severity, until the action of the arsenite of potash brought about a gradual cessation of the symptoms. The very effect of arsenic disproves the theory of embolism, and the existence of an embolus in one corpus striatum can by no means explain—not, at least, in my opinion—the loss of flesh, though it may produce the restlessness. Perfectly clear cases of apoplexy due to hemorrhage and with the seat of the disease in a corpus striatum, if they recover, do not by any means evince any great emaciation, not more than one would expect in so serious a malady.

While I adhere to the view that in my patient the disease was caused by an ascending neuritis, for which, as recovery took place, I can adduce no proof, my main object in publishing this case, is to induce others to report similar cases. The American nation greatly leans towards a nervous temperament, and, I think, it is due to this fact, that we so often notice peculiar nervous phenomena after injuries developing themselves in patients. But only by carefully recording all such cases can we hope to learn their true character.

State Hospital, Ashland, Pa., August, 1884.

SOME OBSERVATIONS ON THE TREATMENT OF COMPOUND FRACTURES OF LONG BONES.*

BY J. H. WOODWARD, M. D.

During the time which you have kindly allotted to me, I propose to discuss a subject with which, I am fully aware, the general practitioner has but little to do. But, notwithstanding the fact that compound fractures are comparatively rare injuries, it may be the lot of some of us to treat one or more of them within a short time. The physician, summoned to such a case, will need all the resources available to enable him to rescue his patient from impending death. Not only is life threatened by every such injury, but, in many instances, the patient must recover, if recover he may, to endure through all his existence the misfortunes incident to the loss of a limb. There are fewer amputations performed now than in former days; not because serious injuries are less frequently sustained, but because limbs that were then sacrificed may now be saved. The treatment of this class of cases, as every one knows, has been modified within the past decade.

It has been my good fortune to witness the results of both the old and the new. It has been my good fortune to observe the effects of a variety of kinds of treatment; and, sad as it may have seemed from other points of view, it has been fortunate for my own instruction that I have been able to observe the fatal issue of a number of cases managed according to methods popular with many surgeons of eminence. On account of these considerations, then, I fain would justify myself to you for drawing your attention to the following observations:

With few exceptions, the subject chosen has been left for discussion to men who have grown gray in the profession.

Much that there is to be read in relation to it has emanated from the reflections of the older surgeons connected with one or more of the great Metropolitan hospitals. But, speaking from my own experience, which I am sure accords with that of a large number of the younger men, I must record it as my conviction, that many of the directions insisted upon by them are not, and never can be, satisfactorily or safely followed in private work, amid the surroundings which are generally present. It is all very well to order a house-surgeon in a well-equipped hospital to see, for example, that discharges from a wound are cleared away three times during the day and as often during the night. It is all very well to impose upon him directions for treatment that will keep two or more trained assistants busy night and day. In hospitals there are many to assist and many to watch every change in the case. But in private practice, even in the homes of the rich, how different are the surroundings! and how futile the attempt to carry out there all the necessary details of those methods! The visiting surgeon to the hospital does not realize how great is the amount of work performed in the execution of his orders. It falls to the lot of the younger men to know all the drudgery of the institution; and, with certain restrictions, it becomes proper for them to lay bare their thoughts.

So much by way of preface, gentlemen, and now, with your permission, we will enter upon the subject before us.

Clinically, we may roughly classify compound fractures under three divisions, namely:

1. Cases in which primary amputation is necessary.

2. Cases in which amputation may be delayed until conservative treatment has been faithfully tried.

3. Cases in which the injured member may be saved—the question of amputation arising, if ever, only when unavoidable poisoning of the blood has begun.

1. Cases requiring primary amputation.

Oftentimes it is not difficult to decide whether the patient must submit to amputation. Those injuries which fracture the bones, lacerate the soft parts, rupture arteries and nerves, and leave the extremity attached to the body by mangled tissues, present no questions respecting the nature of the treatment to be adopted. The sole deliberation called for by them is upon the selection of the proper time for the primary operation. It is the general opinion of surgeons that amputation should not be performed during the state of shock. In the vast majority of cases, the wisdom of that rule nobody will attempt to gainsay. But there is a class of cases in which the presence of the injured member prolongs and deepens the shock. There are other cases in which troublesome hemorrhages from arteries too small to be found in the mangled tissue, renders it imperative to apply the tourniquet. In the latter set of cases, if we were to wait always until the patient had rallied, the tourniquet must remain in position for hours. In both sets of cases, we should not wait more than two or three hours. During that time stimulate the patient by the hypodermic method; and, hav

*Read before the Rutland County (Vt.) Medical and Surgical Society.

ing delayed as long as the condition of the limb will permit, operate as rapidly as possible. When the hemorrhage is not serious, even though the main arterial trunks are lacerated, the tourniquet need not be used. Of course, the lacerated vessels should be ligated. A wet antiseptic dressing may be made to compress the oozing surface, and, if necessary, the surgeon may wait twenty-four hours before operating.

2. Cases in which amputation may be delayed until conservative treatment has been tried.

The second class which we have made, includes those cases of compound fracture which test more thoroughly the skill and patience of the surgeon. Every detail in the history, every thing about the fracture that can be ascertained by the most careful examination, must be studied attentively and judged upon its merits. The age, general health and habits of the patient must be given their share in the evidence pro or con. Then the surgeon may decide whether conservative treatment should be attempted; and that decision must be made in the knowledge of the dangers that must be averted, and with sufficient confidence in the methods to be employed.

The nature of the causes of these fractures determines a wide difference in the cases. In the majority of instances, a compound fracture produced by direct violence is much more serious than one produced by indirect violence. When direct violence is the cause, the skin, muscles, fascia, blood-vessels, nerves, periosteum, and bones are contused to a greater or less degree, and that always affects the process of repair. Sometimes the fracture is comminuted. Sometimes the wound in the integument is small, but the tissues beneath the skin are so badly contused and, perhaps, lacerated by the sharp fragments, that a case which, to an inexperienced eye, may appear to be an ordinary one, is, in reality, one of the gravest kind. This contusion should be looked for, and if found, the extent of it should be carefully estimated. With it is frequently associated undermining of the integument, making pockets beneath the skin, sometimes in the muscles, and sometimes in the intermuscular spaces. It is as important to explore the wound for them, as it is to examine the fractured bone itself.

Serious hemorrhage in cases of compound fracture is common enough; but, in the majority of cases, the hemorrhage should not alarm the physician. The bone bleeds more or less and there is generally venous hemorrhage that may make some "show" of being serious, but it will cease without any interference in a little while, after the deformity is reduced. Even wounds of large veins need not determine you to amputate.

The following quotation from Billroth's Surgical Pathology (p. 212) will give you his opinion of the importance of injuries to nerves and blood-vessels in this class of fractures:

"Large nerve trunks are rarely torn in fractures, and when they are, it does not seem to have much effect on the cure; and experiments on animals, as well as observations on man, show that bones may unite normally in paralyzed limbs. Injury of large venous trunks, as of the femoral vein, causes hemorrhage, which may be readily checked by a compressing bandage, it is true, but may prove dangerous when the blood effused between the muscles and under the skin begins to decompose.

Rupture of the arterial trunk of a limb occasionally leads at once to considerable arterial hemorrhages; but this is not a necessary sequence; for, as previously shown, a thrombus quickly forms in the crushed artery, so that we do not always have excessive hemorrhage. But, if from the nature of the hemorrhage we recognize the rupture of an artery, according to principles already laid down, we should either attempt to ligate the artery at the wound, or else at the point of election. Rupture of the femoral artery with fracture of the femur is found by experience to be followed by gangrene, and is an imperative indication for amputation, while in a corresponding injury of the arm recovery may result or gangrene may follow. In fractures of the forearm or leg, even if one or both arteries be ruptured, recovery may take place.

Furthermore, there are on record three cases of simple fracture, in which diffuse aneurism formed, and in which the femoral artery was ligated. The patients recovered perfectly. Petit ligated the anterior tibial artery in a similar case, and the patient recovered. These facts are positive evidence that serious injuries to blood-vessels do not always afford a sufficient justification for the removal of a limb. [See Ashhurst's Encyclopædia of Surgery, vol. iii., pp. 162, 163.]

Laceration and contusion of the soft parts may be great enough to indicate imperatively a primary operation. The periosteum may be stripped from the fragments to such an extent, or it may be so seriously contused that it would be futile to delay amputation beyond the state of shock. To save a limb that will heal in such a condition that it will not be a serviceable member is not good surgery. But we should hesitate to condemn a limb on such

ground; for it is far better to fail in attempting to save a limb by conservative surgery than to amputate unnecessarily. These considerations must be borne in mind and influence our decision respecting the treatment of these cases. Experience with the healing of wounds will tell pretty nearly what result may be expected. The statistics collated years ago are not reliable now. In order to see the merits of a bad compound fracture and decide how great is the hope of a satisfactory termination, it is necessary that the surgeon should know what may be accomplished by the modern methods of dealing with wounds. Nature will accomplish more, with a little judicious assistance, than we are accustomed to think.

And I am confident that in many doubtful cases the surgeon will not regret having postponed an amputation to try faithfully the conservative antiseptic treatment.

Suppose a compound fracture of the tibia; the fracture in the tibia comminuted moderately, the upper and lower portions of the shaft separated by a long oblique line of fracture, the one overriding the other; the soft parts of the anterior and outer side of the leg, presenting a large contused wound extending into the muscles; the fibula fractured, but not compounded; both arteries intact. Your imagination can hardly lead you astray as you attempt to form a picture of such an unpromising case as that. Many surgeons would have amputated the limb at once. It was the most serious compound fracture of the leg that I have ever seen managed conservatively. Dr. F. Lange, however, saved the limb by means similar to those I shall describe later on, and taught many of us a startling lesson in the treatment of such cases.

[And here pardon me a digression. There is no surgeon in New York who has done so much for the recent advance in the surgical treatment of a great variety of cases as Dr. F. Lange. The older surgeons, as well as the younger, are indebted to him for more than will ever be acknowledged. He needs no eulogist, however. It was he who taught us in Bellevue Hospital all that we know that is most reliable in the aseptic management of all sorts of wounds. From Bellevue that knowledge spread to other hospitals, until now the journals contain articles showing how well or how imperfectly the lesson has been learned elsewhere. Other men have claimed the honor of bringing about this great change, but to Dr. Lange is due all the glory of initiating an advance so great and so brilliant.]

Having determined to attempt to save the limb, what method of management should you select? I do not know what the opinion of the profession in this country may be, in regard to the causation of the various accidents which befall many wounds. Whether you believe in the power of germs (bacteria, micrococci, etc.,) to poison, by their activity, the wound or the patient's blood, I do not know. My own belief in relation to this subject is clear enough. And daily observations, made through a considerable period, have uniformly strengthened my conviction, that the theoretical conclusions and classical results of the treatment based upon them, are scientifically associated. In the majority of instances, the bad behavior of wounds is due to the action of micro-organisms. Septicæmia, pyæmia, and allied affections are always the consequence of their activity. And suppuration, which is too often a serious burden for the patient, also *generally* depends upon those organisms.

You may dissent from this opinion, but I do not believe that any one will attempt to maintain that the treatment based upon the germ theory is not followed, when conscientiously and intelligently carried out, by results more brilliant and more uniformly excellent than any other sort of treatment can boast of. Whether by virtue of the contagion of fashion or the force of conviction, surgeons seldom dress a wound now-a-days without employing some antiseptic or other.

The various methods set up against the aseptic method are all antiseptic more or less. And in some notable instances the prominence accorded to the antiseptic furnishes an explanation of the success attained.

Prof. T. M. Markoe published an article in the *American Journal of Medical Sciences*, for April, 1880, entitled "Thorough Drainage in Treatment of Wounds." He employed that method in a number of compound fractures, and the patients all recovered very satisfactorily indeed. But they did well *because* the cases were managed antiseptically. His treatment is an efficient antiseptic treatment. In private practice, however, and in the country especially, it could not be attempted without exposing the patient's life unnecessarily. Methods which permit that healthy suppuration which produces "laudable pus," are objectionable, because they permit that drain upon the patient's vitality to take place. Suppuration that was formerly regarded as laudable may now be regarded as at least unnecessary.

In the *Journal* of the American Medical Association for June 21, 1884, you will find an article on compound fractures. The author cites 144 cases

but his, like statistics in general, are very deficient in many important respects. I have seen the method he advocates applied in his own wards. It is an antiseptic method, but it is not aseptic. And it is a just criticism to offer the fact that his patients uniformly manufacture more pus than do those of any other surgeon who visits Bellevue Hospital. Further objections might be urged here, but since they are mentioned incidentally at another part of this paper, it is best to postpone all discussion of them until a more convenient time.

The practice of sealing the wound in compound fractures with cotton and collodion, or with cotton saturated with blood and dried, is familiar to every one, and is, I believe, quite popular.

In the Roosevelt Hospital, New York city, that practice has been tried more extensively than in any other institution of the sort that I am acquainted with; and, I am sorry to say, it has been attended with success, even in some very unpromising cases. Such success is misleading. I remember very distinctly a compound fracture which was sent to Bellevue one night from Roosevelt Hospital. The patient was delirious, with a temperature of 102°. He was a German, who had been accustomed to drink a pint of beer daily. For that reason his delirium was said to be due to acute alcoholism. I do not question the diagnosis. The following evening the apparently elaborate dressing was changed, and it was discovered that the wound had been sealed. The position of the fragments was exceedingly bad, chiefly because it had not been possible to keep the patient quiet. He had been delirious two days only, and had been violent a much shorter time. It did not seem possible to any of us that the movement of the fragments could account for the condition of the limb, which was so bad that it seemed inevitable that the greater part of the integument on the anterior surface of the leg must slough away. The wound through the skin was a small one, and that fact may have deceived the surgeon. On the third day the house-surgeon operated upon the case in the presence of two surgeons well-known in New York city. Although the general and local condition of the patient had improved since his admission to Bellevue, the limb at this time looked so unpromising that surgeons of large experience remarked that, a few years ago, amputation would have been performed without a question. The house-surgeon enlarged the wound, sutured the bones with silver wire, and finally, in order to relieve tension, he made two long incisions on either side of the leg from its lower third to the popliteal space. The most strict antiseptic precautions were observed, and a closed antiseptic dressing applied. The progress of the case after this was very satisfactory indeed. The temperature-range was favorable all the time, the patient's local and general condition improved rapidly and steadily, and now, more than six weeks after the operation, he is out of danger and his fracture is quite firmly united.

The sealing process in this instance caused retention of blood and serum. And no splint, by itself, could hold the fragments in proper position even under ether. It was the general opinion of all who saw the case, that the bad behavior of the fracture was chiefly owing to the treatment adopted at the outset. The patient's marked improvement in every particular, which ensued directly after the case was operated upon, is confirmatory evidence that our judgment was sound.

I remember another compound fracture of the tibia, due to direct violence, presenting a small wound communicating with the fracture. It was treated by sealing. The temperature range in this case was never satisfactory, and after one or two weeks the fever rose so high that the sealing was removed.

Thorough antiseptic precautions were taken to disinfect the wound, which was then dressed antiseptically, but was neither enlarged nor drained. The patient in a few days became apathetic, then delirious, and finally died, after a short illness, of septicæmia.

Very few cases of compound fracture are suitable for the practice of sealing. It is unjustifiable to seal any wound produced by direct violence. It is unjustifiable because, unless the wound be enlarged and free drainage of every part of it provided for, one is apt not to thoroughly disinfect a certain number of cases. In a wound rendered aseptic, sloughing may take place without danger of blood-poisoning. But, in contused wounds that are not aseptic, there is suppuration, and, too often, decomposition of the discharges. This sealing process is unsuited to all cases in which the bones are comminuted, and all in which there is much hemorrhage. Since the method favors retention of blood and serum, which, by their presence, increase the tension and consequently the danger of inflammation, and since there are other methods which protect the patient more thoroughly against the consequences of fermentation of the wound, it seems to me that the practice of sealing compound fractures should be universally condemned, and discarded altogether.

In all cases some method of treatment, consist-

ing in the use of antiseptics, should be relied upon. Perhaps it is true that a certain number of wounds are not infected, and do not require to be *dis*infected. But I have never read of, nor have I ever been told, the means by which any one may select them. The greater the care with which you make the primary disinfection, and the more scrupulous your attention to all the details of the aseptic-antiseptic treatment, the more satisfactory to every one will be your results.

The treatment that I am about to describe affords, when properly carried out, nearly perfect protection against septicæmia, pyæmia, erysipelas, and every other form of blood-poisoning. It either prevents all suppuration in the wound, or reduces it to insignificant proportions. It prevents inflammation of all sorts, and it is most comfortable to the patient and surgeon. The former is not depressed and exhausted by a febrile movement, nor is he irritated or frightened by frequent manipulations about the wound. The surgeon must be watchful, but he may be pretty confident that everything will terminate to his satisfaction. Now and then a case does badly; and, as a rule, the surgeon may blame himself for it.

Generally speaking, it is altogether best to anæsthetize the patient before attempting to dress one of these serious cases. The same rules for administering ether hold good for these patients as for others. Of course, stimulate the patient until the shock has passed away, and then the anæsthetic may be administered without incurring any special risk.

Every instrument, every sponge, in short, everything that may touch the wound, should be thoroughly purified of all septic matter. And, excepting when in use, they should be kept immersed in $\frac{1}{30}$ carbolic solution. The limb should be placed on a rubber blanket arranged so that the water will run into a bucket and over the blanket. Just prior to beginning the thorough examination of the fracture, you should spread towels, recently wet in $\frac{1}{1000}$ solution of corrosive sublimate. The operator and his first assistant should thoroughly cleanse their hands with a nail brush, and disinfect them both in the beginning and after handling any unclean thing (as bedclothing, etc.) A basin containg $\frac{1}{40}$ carbolic solution should be within easy reach for such purposes.

(*To be continued.*)

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. Seelye, A. M., M. D.

Cerebro-spinal Meningitis.

Patient is a boy 15 years of age, a German, single, and a glass-finisher by trade. Was admitted January 9. Both parents are subject to attacks of rheumatism, but they have five other children, none of whom have ever had it. Patient occasionally uses beer and stronger drinks, but not to excess. Has never been exposed to gonorrhœal or syphilitic infection. Three years ago he received a hurt upon the left knee, but it did not trouble him much, and he thought it of little consequence. Since then he has enjoyed good health until three months ago, when he had an attack of rheumatism in the ankle-joint, which became swollen and painful. In May last, however, he thinks he had fever and ague, and he says that this returned at the time of his rheumatic attack three months ago. Every day for three weeks he had a chill, followed by fever and sweating, which caused him to become weak and greatly prostrated. After this he got better and went along well until last Friday, when he was seized with an excessive pain in the front part of his head; and soon after he began to vomit, and he continued vomiting at frequent intervals all that night. The vomiting was markedly projectile in character. The bowels have not moved since. He has had a moderate cough, but a constant and intolerable headache has been the symptom of most importance, and he says that it has driven him almost crazy. About a half day after these symptoms began, he noticed a stiffness about the muscles in the back of the neck, which has steadily increased until he can now not move his head without great pain. He sometimes sees things double. Two days before his admission his head was so much drawn back in a state of opisthotonos that he says he could not see his own toes. On admission his pulse was 112, respiration 32, and temperature 104.2°. His prominent symptoms since he came in have been nausea, vomiting, groaning with the intensity of the frontal pain and a cough. Besides there was found a mitral regurgitant murmur. The vomited matter was greenish, and contained mucous and biliary ingredients. At times his mind wanders, and he has a mild delirium. A good deal of the time he lies in a stupor, but from this he can easily be aroused. He has a dry cough and a dry and sore mouth. The muscles of the neck are so rigid that he cannot turn the head to the left, nor bend it laterally without great pain. There has been a slight amount of external strabismus, which is constantly increasing. He is most delirious at night. The conjunctiva upon the left side is markedly congested. The knee, elbow, hip, and ankle joints have become stiff to some extent. There are some dry rales and other rhonchi heard upon auscultating over the lungs. The urine is acid, with a specific gravity of 1029, and contains urates, but no albumen.

Gentlemen, there is nothing of special import-

ance in this history until we come to the time when he suffered from an attack of rheumatism in the ankle-joints, about three months ago. From that, and from the daily attacks of fever, he suffered for three weeks. Then there was an interval of fair weather for a little time. But upon Friday of last week he was seized with the onset of the disease from which he is now suffering, in the shape of a severe frontal cephalalgia, nausea, vomiting, and stiffness of the muscles at the back of the neck; and at one time opisthotonos was so extreme that, as he expresses it, he could not see his toes. He was brought in here upon the ninth of this month with a temperature of 104.2°, a respiration of 32, and a pulse of 112. When he came in he was suffering, as he had been from the beginning, from extreme headache, nausea, and vomiting, and from tenderness in the back of the neck, and from extreme pain whenever any effort was made to flex the head upon the trunk or to turn it towards one side. He is delirious at times and soporose at others. But the delirium is not active, and he can almost always be easily recalled to consciousness by speaking to him. It is not therefore, a violent delirium. There is still another special symptom here, and that is a disposition to grimace, which you have probably already noticed while standing here at his bedside. When I disturb him a little by touching him upon the forehead you observe that there is not merely an expression of pain, but a knitting of the brows. And this, with an occasional twitching of the lips and a movement of the nostrils, has been noticed as a striking objective sign ever since he came in, and it is a common symptom in this disease. Also note the character of the temperature, pulse, and respirations since he came in. There has been about all these vital signs a marked irregularity. He came in with a temperature as high as 104.2°, but this was partly due to the agitation produced by his removal: it fell the day after to 102.3°, and has not risen since above 103.6°. The variations in the temperature do not follow any regular course such as is observed in the daily variations in the essential fevers. But there is great irregularity occurring two or three times in the twenty-four hours. For example, to day at 6 a. m. the temperature was 101.2°, and at 9 a. m. 101.6°, and at 1 p. m. 101.8°; while yesterday at one time it was 102.6°, and in the evening 101.3°. It is sometimes higher in the morning, and not so high in the evening, and again it is sometimes lower in the morning and high in the evening, and there is no regularity about it. And the same thing is true of respirations. At the time of his admission on the ninth, they were 32 per minute, and later 34, and on the tenth they were 16, and yesterday 32, and to-day they are 28. The pulse also varies a great deal. On his admission it was 112, then 100 the next day, and 104 the next, and at noon to-day 100. And I have no doubt that these same variations in the pulse are observed even in the quarter minutes. So the variation does not seem so marked in the record as it really is. Now this irregularity in the vital signs is one of the characteristic features of this disease; for his disease is a meningitis which involves both the cerebral and the spinal meninges, and it involves a locality in which the irritation affects the centres which control the respiration, temperature, and pulse. Another very interesting and characteristic feature which we have here, is the arthritic lesion. Whether the articular disease of three months ago was of nervous origin, and one of the prodromata resulting in this malady, or not, I am not prepared to say. But since he came in, he has had a rheumatic affection of the knee-joint, and it is not at all improbable that he will have other joints affected in the same way before he gets through. These articular affections occurring in the course of cerebro-spinal meningitis constitute one of the most interesting features of the disease, and they are apparently so far a demonstration of the theory of the spinal origin of articular lesions. You all doubtless know that this is a point about which there is now considerable discussion going on, as to whether articular rheumatism is a disease having a spinal origin. There are some things which seem to point to some such association. For example, in Potts' disease it is commonly noticed that the joints below the seat of the spinal lesion are the ones to suffer, and in locomotor ataxia this same peculiarity is noticed, and in acute diseases of the membranes of the brain and spinal cord, you not infrequently find in some epidemics the occurrence of this articular complication.

There is another sign which is common in this affection, but which he does not present, and that is a cutaneous lesion. This disease has also been called spotted fever, from the fact that when it has occurred in epidemic form an eruption more or less extensive has commonly accompanied it. This eruption varies a good deal in its characteristics. The most striking peculiarity is its petechial character, and the spots are sometimes discolored by a cutaneous hemorrhage, forming blood-stains, and it sometimes simulates the maculated eruption of typhus fever. Or the eruption may be in the form of broad patches of ecchymosis; or sometimes there may be an erythematous rash simulating that of scarlet fever or measles. So we have really, when we come to study the cutaneous lesion of meningitis on a large scale, a polymorphous eruption, so to speak. But there is always more or less tendency for it to assume the hemorrhagic form.

Now as there is considerable variation in the constancy of the articular lesions, so there is also in the cutaneous lesions, and these objective signs are not invariably present. You may see many cases in which there are no cutaneous or articular symptoms, or either may be present and the other absent. It is probable that these variations are determined by the location of the central inflammatory lesion. There is probably some nerve-centre the irritation of which produces cutaneous disturbances just as there are centres which when irritated provoke articular lesions.

The special interest of this case is in the fact that it illustrates the important characteristics of this malady, in the cephalic pain, and the stiffness of the muscles in the back of the neck, and in the moderate degree of delirium and the soporose condition, and the irregularity of the pulse, respiration, and temperature, and in the tendency to involuntary twitchings of the muscles of the face. He lies, as you see, with his head a little inclined to the right, and he resists

any attempt which is made to turn his head to the left, and pressing upon the back of the neck or making any effort to flex the head upon the chest causes him severe pain.

There is another symptom in the history of this case which I wish you to note, and that is the nausea and vomiting. This is a frequent, but not invariable accompaniment of this disease. But it has been a troublesome complication here, and has interfered somewhat with the treatment, so it has been necessary to use the hypodermic method altogether for the administration of medicine, and the rectum for the food and nourishment.

The treatment adopted in this case is the one which for the past two or three years we have been accustomed to use here, and which has given some degree of satisfaction; but I must confess that from its frequent failures to produce any benefit there is some reason to doubt whether its success in those cases in which it has seemed to succeed is a genuine illustration of its therapeutical effects. Ergot, you know, is supposed to have some influence in controlling the circulation in the cerebro-spinal cavities, and in accordance with that theory it has been administered in such cases as this. But I am not prepared to speak as regards its utility. It is one of those remedies, the value of which is at present under discussion. It certainly has some extraordinary effects upon certain nervous diseases, where its utility is explained by its effect upon the circulation. It may really act by controlling the circulation, or it may act in some other way. But that it does frequently act favorably in cerebro-spinal affections there is no question. I only have some doubt as to its utility in this disease, because where it has been tried its effects may have been modified by other drugs, which have usually been administered with it. Again, there is no question but that there is in all acute diseases a tendency to recovery, which is more or less successful independently of any remedies whatever. So we should receive the evidence of the utility of any medicine in acute diseases with some caution. In these cases "post hocs" are not always "propter hocs." I would treat this disease with ergot now, though, perhaps, in a year from now I would not; for new remedies are constantly being tried, and something promising greater success may be introduced within a year which will entirely supersede this one. This diversity of remedies for a single disease has been especially noticeable in the history of the treatment of rheumatism.

Fashion sometimes favors one drug and sometimes another; and the success of any treatment, so far as we are able to judge, should not be accepted without considerable doubt. For we can not say certainly that the result is due to the treatment.

Apoplexy.

This, gentleman, is the case you saw last week (see page 201) of the man who had aphasia in connection with hemiplegia. When you were here he was in a state of semi-consciousness, and we were not able to arouse him sufficiently to make him speak, though there was not a condition of sound coma. I told you that probably by the time you came again he would have come out of this state of semi-unconsciousness, and we should then know whether he would have what is a common complication of right hemiplegia, namely, aphasia. You now see that he has aphasia, and he only mutters unintelligible gibberish to all questions which are asked him. He understands perfectly what you say, and when asked to raise the right arm he lifts the paralyzed arm with the sound one. This is a very characteristic gesture of hemiplegia.

He has a slight degree of fever: but this is not an uncommon sequence of apoplectic attacks, and it is noticed as a rule that on the third or fourth day after a cerebral hemorrhage a mild degree of fever supervenes, which has been ascribed to the inflammatory irritation which takes place around the clot. This man's temperature was 102.3° yesterday afternoon, and this morning it was normal, and since then it has been rising up to the present time.

He is receiving no treatment other than attention being paid to the food, and to the emptying of the bowels and bladder.

You remember that I told you that he had the triad of cardiac hypertrophy, granular kidneys, and sclerosed arteries, as is common.

General Dropsy.

The next patient is 19 years of age, born in the United States, a student, and single, and was admitted to the hospital last evening. His mother, when living, had occasional attacks of rheumatism, and his father is now alive and well. There is no history of cardiac or pulmonary disease, or of dropsy, in his family. The patient has never had malarial fever, or rheumatism, or gonorrhœa, or syphilis. Five years ago he had diphtheria, and this was followed by pain and swelling of the knee and hip joints, and the swelling spread down the whole thigh. He complained chiefly of the pain in his right hip joint. He never had any fall or other injury to account for it. For the past five years the pain in the right hip has been severe and constant in character, and has been worse at night. He has been treated for this by electricity, and by local applications of every variety. One year ago suppuration began to take place in the hip-joint, and an abscess formed which finally opened upon the upper part of the outside of the right thigh. Pus has continued to be discharged ever since, and there are now two or three discharging sinuses at this point. He says no pieces of bone have ever come away with the discharges. The head of the femur used to sometimes slip upwards out of its socket, but this dislocation could easily be reduced. The right leg has gradually become atrophied until it is now only half the size of the left. He has been subject to dyspepsia, and would often have attacks of diarrhœa after any slight irregularities of diet. He has not been troubled with piles. For the past three weeks he has been costive, but for the last three or four days he has had a diarrhœa from taking some pills. Three weeks ago both feet and legs became swollen, and he became troubled with a cough and shortness of breath, and a feeling of oppression in the chest, and with pain in the lumbar region, and with attacks of vertigo. He noticed upon rising in the morning that his face had a puffy appearance, and this was

especially marked just under the eyes. He had no œdema anywhere before three weeks ago. But now, besides the general anasarca, his scrotum and penis are infiltrated enormously. He can move his right leg better than he could a year ago. On his admission his temperature was 98.7°. His urine was of an amber color, and acid reaction, and had a specific gravity of 1.018, and was one-tenth albumen, and contained fatty hyaline and epithelial casts of various sizes.

Gentlemen, the interest of this case begins with the attack of diphtheria, which he says he had five years ago. But he is not very clear as to the nature of this attack, and so I asked him if it might not have been scarlet fever, because this malady which came on soon after is more commonly a sequel of scarlet fever than of diphtheria. I have never seen a case of scrofulous bone-disease coming on after an attack of diphtheria, but I do not say that this may not occur. He says that soon after the diphtheria ended he had pains of a rheumatic character in the hip and knee of the right side. But this was really not so much rheumatism as a morbus coxalgia, as it is called. And pain referred to the knee-joint is one of the common symptoms of an irritation in the hip-joint. There has always been some embarrassment of movement in this hip-joint ever since the trouble began, and there has been pain extending from the hip down to the knee. He says that he was obliged to walk on crutches until a year ago, and since then he has used a cane. This disease finally terminated in the production of an abscess a little below Poupart's ligament upon the anterior and outer portion of the thigh, and the sinuses leading from this are still discharging. The disease in the hip-joint we are not however concerned with, except in so far as it relates to the causes of the disease from which he is now a sufferer. He comes into the hospital for relief from a general dropsy; and the characteristic features of a general dropsy are very well illustrated here. The lower extremities are very markedly swollen, and the scrotum is greatly distended with fluid, and the penis is much enlarged and distorted, and has the characteristic corkscrew appearance which is often seen as the result of œdema, and there is general anasarca of the whole body to a marked degree. There is considerable fluid in both pleural cavities, but I do not get any satisfactory evidence of fluctuation in the abdominal cavity, though there may possibly be a certain amount of fluid there. Now we are to determine what is the cause of this general dropsy.

Upon physical examination, I find no alteration in the heart-sounds, and no evidence of any considerable cardiac hypertrophy. The apex beats inside of the nipple-line and in the fifth intercostal space, and the area of præcordial dullness is not increased, and the valves are not insufficient. So we can not attribute this general dropsy to any disturbance at the centre of the circulation. I find considerable splenic enlargement, but no particular change in the area of hepatic dullness, and there is no enlargement of the abdominal veins, and nothing, therefore, indicating any obstruction in the portal circulation. Now, therefore, having eliminated the cardiac and hepatic causes of dropsy, we yet have left the renal explanation. The urine has already been examined and has been found albuminous, and to contain an abundance of casts of all varieties, and the amount passed has been small. From these facts I think it is fair to infer that he is the subject of a parenchymatous nephritis and probably, also, of a certain kind of degenerative change which is not inapt to occur in connection with chronic suppurative conditions. The lardaceous kidney is the regular result of protracted suppuration. And patients with hip-joint disease and Potts' disease, and who have abscesses which continue to discharge for a long period of time, and especially abscesses which are due to necrosed bone, are not inapt to suffer from this amyloid form of degeneration. In the dropsy which occurs in connection with this form of kidney disease you will always notice a more or less anæmic condition of the patient. And so you see that this man has a pale skin and waxy lips, and I suspect that this dropsy comes from the anæmic and watery condition of the blood, which prevents those interchanges between the tissues and the blood, which depend for their activity upon the healthy state of the blood and the tissues.

The treatment of such a case depends upon the carrying out of two indications, namely, to improve the quality of the blood, and to increase the eliminative power of the kidneys and the supplementary functions of the skin and bowels. You observe that the doctor has bandaged these limbs. And it is probable that from this simple measure, in connection with rest in the recumbent posture, there would be a considerable diminution in the dropsy. But this elimination will be increased by the administration of diuretics, and by paying attention to the diet. And this is a better plan than to employ extreme diaphoretic measures, and it is also best at present not to exhaust him by excessive purgation. The occasional administration of diuretics and laxatives, and the employment of pressure and of good food and ferruginous tonics to improve the quality of the blood, is the best plan of treatment. And with this combined treatment of pressure, food, medicine, and tonics, you will probably see an improvement in a short time.

His present condition is a perilous one, because it is liable to give rise to dropsical effusions in locations where they may do mischief. It is quite safe for a fluid effusion to collect beneath the skin or within the peritoneal cavity, but it is not so safe to have it fill the pleural or pericardial cavities, where it may interfere with the action of the lungs and heart. And when you come to the subarachnoidean space, you see it needs but a slight amount of œdema to cause a great deal of mischief. So it is important first of all to improve the general condition of the patient by nutritious food and iron. And this is better than to exhaust him by violent purgation and diaphoresis, which may disturb the stomach and so defeat the principal object of treatment, which is to improve the general nutrition.

—The authorities of Vienna have sent a commission composed of two physicians and three sanitarians to Toulon and Marseilles, for the purpose of investigating the cholera epidemic.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, February 14, 1884. The President, Dr. Tyson, in the chair.

Aneurism of the Left Ventricle.

Presented by Dr. W. E. Hughes.

To the kindness of Dr. M. B. Musser I owe the clinical history of this case, and the privilege of presenting the specimen to the society.

Mr. P., æt. 58 years, healthy, with the exception of slight pain in the region of the heart on vigorous exercise, was attacked September 20 with left hemiplegia. Motion was completely lost, sensation somewhat impaired, but by no means lost. The attack was rather sudden, and was preceded for some days by slight dizziness. There was no loss of consciousness. After treatment lasting over more than a month, he is so far recovered as to be able to walk with the assistance of a cane, when he was seized one night, while in bed, with a frightful attack of angina pectoris. During the next two or three days the attack was repeated several times, and at the end of that time there was a very plain double pericardial friction sound heard over the whole cardiac area. From this time on the anginal attacks were neither so frequent nor so violent as before. He fell back dead, November 15, while sitting up in bed to take a glass of water. Before the pericarditis had developed, the heart had been carefully examined, with the result of finding no murmur. The area of cardiac dullness was enlarged, and the heart's impulse weak and diffuse. The pulse was weak, ranging from 75 to 80 in the minute, and very little accelerated during even the severest angina. The urine contained a small amount of albumen. No microscopic examination was made. There was at no time any œdema. Autopsy 36 hours after death. Body very fat. Rigor mortis moderately well developed. Abdominal and thoracic organs decomposing rapidly. Brain is larger than the average, very heavy, and much convoluted. All its larger arteries are atheromatous, in places converted into rigid tubes, but nowhere is there any interruption of their lumen. No lesion of the brain substance. Some opacity of the pia mater, more marked over the right hemisphere anteriorly. In the meshes of the pia mater a large amount of straw-colored serum, most abundant about the motor areas on the right, and here the serum is tinged with blood, though there is no true clot. Very little serum in the ventricles. Lungs are congested; no lesion of their substance. About a quart of serum in the left pleural cavity; less fluid in the right, and firm adhesions over its upper half. Universal pericarditis. Cavity of the pericardium is almost obliterated by easily torn adhesions; where it is not obliterated, there is a small effusion of flaky, sanguinolent serum, and the pericardium is ribbed by a deposit of lymph. Heart is large, left auricle dilated, ventricle enormously dilated and hypertrophied, its wall one and a half inches thick; right side very little changed. In the left ventricle, involving the interventricular septum and the wall about the apex, is a saccular dilatation capable of holding at least two fluid ounces, developed by a giving way of the heart wall. This cavity was filled by a firm old clot, containing a cavity as large as a filbert, filled with grumous pus. The endocardium in the aneurism had been totally destroyed, and the clot was in places firmly adherent to the exposed and thinned muscular tissue. In the anterior wall the tissues had completely given way over a very small area, and the rupture was filled by the clot, which projected slightly into the pericardial sac. A similar condition existed in the septum, the clot here projecting one-half inch into the right ventricle. Owing to the clot filling these ruptures, there was no communication between the cavity of the left ventricle and that of the right ventricle, or of the pericardium. Heart muscle is fatty. Aorta is slightly atheromatous, and its valves rather rigid, though competent. Other valves healthy. Coronary arteries not atheromatous. Liver enlarged, congested, slightly cirrhotic. Kidneys enlarged, congested, cortical substance increased in volume, small spots of fatty degeneration, capsule strips off easily.

Dr. Bruen thought it was of great interest to note that the location of the aneurism was in the septum towards the apex. This was an unusual site, because when due to ulcerative endocarditis, as was probably the case here, the aneurism is usually situated at the base of the heart, about the attachment of the aortic valves. He had seen a case three or four years ago of aneurism of the heart, the result of ulcerative endocarditis, which was situated at the apex, but it extended towards the left, and did not affect the septum. In this case the pericardial cavity was completely obliterated at the site of the aneurism, where the pericardium formed the aneurismal wall. I tapped at this joint for a pleural collection, but only withdrew of blood when I desisted. Instead of doing harm the tapping afforded relief, and the pleural and other dropsical effusions were absorbed, the patient dying fully two years after the operation.

Dr. Tyson thought that the disease being situated at the point, it rather pointed to endocarditis of the cavity than to the ulcerative form. This had resulted in the formation of one of the so-called tendinous spots, which gradually yielding the aneurism had formed. The rupture might have been of some standing, as these interventricular ruptures are stated to be not very dangerous, and compatible with considerable prolongation of life.

Dr. Hughes said there really had been no communication between the heart-cavities as the opening was blocked up by a clot which was evidently old.

Pernicious Anæmia.

Presented by Dr. W. E. Hughes.

George G. C., white, æt. 45 years, a clerk was admitted into the University Hospital, February 4, in an intensely exhausted condition, with a history of an illness lasting over two and a half years. He had lived for the last twenty years along the banks of the Potomac in the midst of malaria, and had had ten years ago intermittent fever lasting two months. His habits were all regular, and he denied any venereal taint. For the last three or four years he has been much

worried by family and business affairs. His father and a paternal uncle and aunt died of apoplexy, his mother and all her brothers and sisters of phthisis; of his own generation all the members were perfectly healthy. He was unmarried. Till he went into the army during the war, he was well and strong; while there he had an irregular malarial fever, from the consequences of which and of exposure, he never thoroughly recovered. Two and a half years ago he was attacked, without any obvious cause, by diarrhœa, and though his appetite and digestion remained good, he lost flesh and strength rapidly. His urine at this time was much increased in quantity, and was said to contain sugar. The diarrhœa continued for some months, and he became reduced almost to a skeleton; then it ceased, the urine fell to its normal quantity or even below, and he regained much of the flesh he had lost, though his strength and general condition remained far below par. After some little while of this apparent improvement, he again commenced slowly to fail. Till within three months the functions of the gastro-intestinal organs were apparently well performed; since then he has had some slight heaviness in the epigastrium and flatulence soon after eating a hearty meal, and the bowels have shown a tendency to constipation. Since last June he has been unable, from intense weakness, to perform any manual labor. There has been no hemorrhage. On admission, he was too weak to raise himself in bed, intensely anæmic, the whole cutaneous surface pale straw-colored, the veins showing through as pink lines, the mucous surfaces scarcely distinguishable from the skin, and moderately emaciated. There was no œdema. The heart action was excessively weak, with the apex beat in the usual position, and over the body of the heart was heard a soft blowing systolic murmur, lessened in intensity by firm pressure with the stethoscope. Over the jugulars and the lateral sinuses was heard a remarkably distinct venous hum. With the exception of a slight failure of eyesight, the special senses were normal. He answered questions intelligently but slowly, as though too tired to think rapidly. In the lower extremities he complained bitterly of a feeling of soreness, saying his legs felt as though they had been beaten with a stick. In twenty-four hours he passed one quart of urine, acid in reaction, no albumen, no sugar, specific gravity 1012. Two days afterward, he was weaker and had lapsed into a mild wandering delirium. Examination of the blood gave 665,000 red corpuscles and 6,000 white corpuscles to the cubic millimetre. The red were rather pale, exceedingly variable in size, some of them being twice as large as normal and others very small, and many of them tailed, and otherwise irregularly shaped. Examination of the eye-ground was rendered difficult by his delirium, but no retinal hemorrhage could be detected. He died February 8.

Autopsy (notes by Dr. Formad) *Three Hours after Death.*—No rigor mortis. Moderate amount of soft, flabby adipose tissue, especially beneath the peritoneum. Blood pale, everywhere fluid, no clots even in the heart. The marrow in the tibia, humerus, and sternum was red; the fat in a great measure being substituted by leucocytes and forms intermediate between white and red blood-cells, and a few giant cells. The heart was rather small and very pale, valves were normal. The lungs contained a few calcified nodules in the apices, and were universally adherent to the chest walls and diaphragm. The bronchial and mediastinal glands were enlarged, and some of them calcified. The liver weighed three pounds, and was pale and anæmic. The spleen was normal in size and rather congested. The pancreas was rather diminished in size and indurated. In the left kidney are a few depressed cicatrices not unlike old gummata. Kidneys are with this exception normal and anæmic. The stomach shows some evidence of chronic gastritis. No enlargement of any lymphatic glands other than those noted. Nervous structures were not examined.

Dr. Formad said that the marrow, especially of the upper extremities, showed in a marked degree the typical currant-jelly appearance first described, he believed, by Drs. Pepper and Tyson.

Dr. J. H. Musser said that some of the clinical features of the case were unusual, especially the absence of retinal and other hemorrhages. The heart, too, is usually fatty, and he had thought that medullary bone-changes were unusual, the text-books on pathology containing such statements. He brought the matter forward, as he would like to have some light thrown on such discrepitant statements.

Dr. Bruen thought that the bone-changes occurred more frequently when the case was idiopathic than when there was a malarial history, as in one case seen by him.

Dr. Tyson said that the description of pernicious anæmia in the pathological text-books was very vague, and no mention was made of bone-changes such as described by Dr. Pepper and by himself in Virchow's *Archives* some years ago. This paper seems to have been entirely overlooked.

Dr. Sidney Roberts had had the opportunity of examining the fractured femur of a woman suffering from this disease, when he noted appearances identical with those presented by the humerus before the Society this evening.

Excision of the Shoulder-Joint.

Presented by Dr. C. B. Nancrede.

Anne M., æt. 17 years, was admitted to the Female Surgical Ward of the Episcopal Hospital, May 14, 1883. One year ago last May she fell down stairs and struck her shoulder. She was unconscious for a short time, but was soon able to walk home. The arm did not become inflamed, and seemed, to the patient, well. Nine months after the fall she noticed pain in the shoulder, and an elevated papule formed near the joint, which was opened at the dispensary. This relieved the pain, but left a fistulous tract discharging healthy pus. She attended the dispensary until the 14th of last May, when she was sent into the house, Dr. Seltzer, the assistant surgeon on duty, having touched dead bone with the probe. After admission, she had pain from time to time, gradually increasing in intensity until shortly before operation. Other free openings for drainage were made by Drs. Simes and Kelly. The probe detected an apparent sequestrum with the humerus head.

Diagnosis.—Epiphyseal abscess and strumous disease of the joint. The operation showed complete destruction of the joint, a carious and denuded humeral head, with an abscess about the epiphyseal site containing a sequestrum. The glenoid cavity was denuded of cartilage and toughened. The portion of head and shaft such as you see were removed, while all the glenoid cavity was cut away with the gouge forceps, except where the long head of the biceps was attached. Further details of the operation are unnecessary. The patient was practically well at the end of two weeks.

Excision of Astragalus.

Presented by Dr. C. B. Nancrede.

Elvira ———, æt. 9 years, mulatto, a patient in the Children's Surgical Ward of the Episcopal Hospital, received some slight injury of the right ankle-joint about one year ago, since which the usual symptoms of strumous arthritis have been noted. About two months since, Dr. Packard freely opened the articulation and inserted an oakum seton. Temporary benefit ensued, but February 13, 1884, I found the bone so diseased as to demand excision. This was effected with great readiness by a semicircular incision upon the outer side of the joint, whereby the peroneal tendons were exposed, their sheath partially opened, thus admitting of their being drawn to one side, and the ligamentous structures of the astragalus easily divided. The bone was partially anchylosed to the under surface of the tibia, and nearly all of its tibio-fibular cartilaginous surfaces were bared and carious. All the other tarsal bones seemed perfectly healthy.

Specimens from a Case of Extensive Trephining of the Skull.

Presented by Dr. Nancrede.

These specimens, consisting of nearly the whole right squamous plate of the temporal bone, the inferior angle of the parietal, and a portion of the frontal—in other words, the anterior two-thirds of the temporal fossa, from the orbital plate nearly to the temporal ridge, and from the external angular process of the frontal to a line posterior to the external auditory meatus—were removed by me from a man this day, who had been struck by an iron lever, which caught his head between it and a large beam. Although the depressed area must have been fully an inch deep, yet he walked into the Surgical Dispensary of the Episcopal Hospital, presenting apparently neither motor nor sensory disturbances; pupils and tongue normal. He was at once sent up to the Male Surgical Ward, and I proceeded to trephine, cut away the overhanging shelf of sound bone with the "rougeur," and thus elevate and remove over a dozen fragments of bone. The dura mater seemed uninjured. As the specimens show, the middle meningeal artery must have been torn, and fortunately twisted in removing the fragments, as it was completely surrounded by a bony canal. One branch in the meninges was tied with fine cat-gut ligature, and the wound, as well as a deep scalp cut on the opposite side, were dressed with mercuric bichloride.

EDITORIAL DEPARTMENT.

PERISCOPE.

Abuse of Medicines.

Dr. R. H. Gunning tells us, in the *Edinburgh Medical Journal*, June, 1884, that he believes strongly in the proper use of medicines, as anodynes, emetics, purgatives, diaphoretics, diuretics, etc., but he is also sure of much abuse of them. In 1834, while attending a provincial infirmary, he was struck with the recovery of patients given up to die. The medicines, especially mercury, iodine, and iodides, would be suspended, and the nurse have orders to treat the patient kindly before dying. Immediately recovery would occur! This impressed him, and ever since in practice he has studied whether medicines were doing good or harm. He always held, and still holds, that homœopathy is chiefly the non-abuse of medicines. In the time of Dr. Black and Professor Henderson, of Edinburgh, when this question was once publicly discussed, he challenged its advocates to try 100 cases without medicine and 100 cases treated *secundum artem* against 100 treated homœopathically. He affirmed that, in the first case, the result would be as good as in their 100 cases, and that in the second mode there would be more success. The challenge was not taken up.

In Brazil his success was in cases treated by others. He merely suspended medicines, and put the patient upon hygiene, science, and common sense, correcting ignorance, neglect, and bad habits as to food, air, exercise, baths, etc. His success in chronic cases was great, and people declared that he must have used medicines, and very strong ones, too, for he could not have made such cures otherwise! Some selected cases, further on, will be examples of this abuse of medicine, of diet, and of the horizontal position.

Emetics, purgatives, anodynes, etc., relieve symptoms, but do not go to the root of the matter—error in diet, dress, habits, ventilation, etc. As symptoms recur they have to be repeated. This was the English system of "dose and cure" of the glutton or the beer-swigger, only to "dose and cure" him again. The pills, potions, and powders were the general practitioner's chief income, more than from *honorariums*. But homœopathy, with its metaphysics and paradoxical wonders, and hydropathy, with its hygiene and appropriated science, have done much to correct this abuse of drugs.

Mercury is a good medicine, in its place and in careful quantity, as is iodide of potassium. They will destroy abnormal exudations or organization, and the germs of syphilitic taint, but carried beyond this object they will debilitate and destroy

the body itself. Quinine is a good tonic and specific, but in large doses it is most pernicious. And why in big doses, if small ones will serve? What deafness and loss of sight has it not caused? He has known a child made deaf and dumb with one large dose. He has seen delicate patients take fifty grains in a day and succumb, whose stamina were not equal to ten grains. Small repeated doses can do all, he believes, that large doses do, without doing the mischief.

At first when yellow fever appeared in Rio, the deaths were few when an emetic or castor oil were given early, and the case was left to careful nursing. Since then, and now, a large part of the mortality is from so-called scientific or guessing and heroic treatment.

So with chloral and chloroform—both good agents when carefully used. He knows little of chloral in practice, but he has studied chloroform, and he believes few accidents would occur if it were well understood. When Sir J. Simpson introduced it into practice he made many experiments on dogs and rabbits, and was convinced that it acts directly on the capillary circulation in the lungs, and that death occurs after the manner of drowning when taken too long or too much. If this is so, then it is all-important not to continue its operation too long. A person under water so many minutes may recover, but when so many minutes more it is fatal. The assistant who gives chloroform should understand this, and be most watchful. He should note the quantity used and the time, and it should only be given *on the operating table*, and when all is ready for operating. Thus the time is shortened all possible—the great point. It should not be applied and withdrawn at first, but allowed to have its effect at once. Inattention to this wastes much chloroform, lets the air disengorge the circulation in the lungs, reawakening the patient, and saturates too much the body. A good simple plan is the piece of surgeon's lint laid over the nostrils and mouth, and wetted sometimes if needed. If overdone, fresh air and artificial breathing are indicated, the start for reaction being in the lungs, not in the heart. He could easily restore dogs apparently dead by tracheotomy.

He concludes by mentioning some cases which will show the influence of these four circumstances, namely, diet, position, hot water, and suppression of drugs.

1. A young slave woman had a chronic ulcer on the shin, of seven years' standing. Various doctors had been consulted. Iodide of potassium and calomel were used in succession till most of her teeth were lost, in the belief that she had a syphilitic taint. Caustics and ointments were used externally. The ulcer looked hardened and desperate, and he concluded that, besides the irritating effect of the said medicines, externally and internally, the limb had not had due rest. He simply suspended the medicines, ordered a linseed poultice to keep soft the ulcer, and had her strictly confined to bed. In six weeks, more or less, her health was better, and the ulcer was cicatrized. Here the health was improved, no doubt, from suppression of medicines, but the cure of the ulcer was mainly due to diminished congestion. In short, she had been previously treated without due attention to position, etc.

2. Next, a gentleman consulted him about a large ulcer on the anterior inner part of the thigh, of thirteen years' standing. The whole limb was swollen and anasarcous. He had been the round of the doctors within a large circle. He thought the ulcer had been treated without due attention to position, and declared he would not treat him without a solemn promise that he would keep absolutely in bed. He started him with a dose of comp. powder of jalap to assist the riddance of the anasarca, and to convince him that he was using medicine, for medicine they must have. And, without more than a linseed poultice, diminished diet, and horizontal position, he was well in a couple of months or so. He saw him ten years afterwards, quite well.

3. A gentleman patient suffered from an obstinate stricture of the urethra of some years' standing. He would not allow cutting of any kind, and the surgeons in the city who had attended him were unable to pass any sound. The urine was passed by several openings under and about the scrotum, which was ulcerated, and nearly the size of a man's head. He was ever up and on his feet, washing and passing urine, and he saw a good chance of bettering his state by removing all this source of congestion and exudation. He ordered him, several times a day, a very hot hip-bath to soothe the parts (for nothing soothes like hot water), and then had him put to bed, with strict injunctions not to rise except for real necessity. He made him cross his legs, not to let the large tumor depend, and dressed the raw surface with simple ointment. He also lowered his diet, to facilitate absorption of the exuded matter, and allowed him to drink much rice-water to produce mild urine, as salted, strong urine, irritates the rawness of the urethra and fistulous openings. In a week or so, the swelling was down, as by a charm, the fever gone, and the parts again almost natural. He found he could get his smallest sound into the stricture. In the course of a day or two more he got a very small bulb-pointed one through. By-and-by, he passed other sizes, up to the largest, when the fistulous openings closed, and a complete cure was effected. This was done by keeping him merely horizontal, and the tumor elevated, not dependent. The soothing hip-bath, the reduced diet, and the diluted urine all helped, but the main thing was position, neglected by others more dexterous in manipulation than himself, but less cunning about the importance of position, hot water, and lowered diet.

This same gentleman returned in a similar condition, after more than ten years, declaring that the surgeons of his city could not pass the sound to dilate, and that he could not submit to any incision. He was treated as before; he returned home in two months or so, again cured.

He gives another case. A vicar, looked upon as a saint far and near, had a pimple on the upper part of his penis, behind the gland. His brother-in-law, licensed in Italy, and another, a graduate of Paris, treated him. Caustic was applied, but only inflamed the part more. Then they assumed that it had a syphilitic taint, and gave him mercury till the gums and all his bones were sore. The caustic was continued, and resulted in a subcutaneous fistula. Into this yel-

low wash was injected, and sloughs came away. The more sloughing the more injections, till the fistula reached under the pubic arch. The member got immensely enlarged, and also the glands of the groins. Then it was called cancer, and no hope of a cure could be given by them. The poor vicar made his will, and took the last sacrament of the church. Considered a very saint in the province, the lamentation was great at the prospect of losing him. An English doctor from a distance was called in. Going to dine with a large landed proprietor, and meeting his English collague, he asked to see the patient. He said he could only think of amputation, but that he did not mean to operate on the vicar. When at dinner a note came to him from a devoted friend of the holy priest, wishing him to see him and not let him die. He said he could not go so far, having duties at home. His host said he must go, as the vicar was his cousin. Horses were got ready, and they galloped over the Campo twenty miles by moonlight, in the cold time of the year.

When he saw the sick man, he thought him poisoned with mercury and iodide of potassium internally, and externally by yellow wash. He did away with all, had warm flannels got, and a soft mattress to keep him warm instead of his hard bed and charcoal fire, filling the room with carbonic acid. He gave him a very warm bath with his own hands. With this comfort, and that of warm clothes and a soft bed, and the suppression of irritating drugs, he slept, for the first time for long. He injected warm water instead of yellow wash. The sloughing ceased, and the fistula closed, and the swelling everywhere diminished. In less than two months he was saying mass in the parish church, and the cure was regarded as a miracle.

A large part of this cure was the suppression of irritating, poisoning drugs; but the hot water, and strict lying position, were all great factors in the result.

These are illustrations of what position, the non use of drugs, and the use of warm water and diet, do in medical cases. He gives a recent case, if not of the abuse of medicine, at least of its non-usefulness.

All know how the greatest statesman of the age (Gladstone) has suffered from gastritis and torturing gastrodynia. The routine of mere scientific prescriptions could do nothing for him. At length, in the hands of Dr. Schweninger, of Munich, he has been fortunate. This gentleman has discerned the case better, and enforced strict diet and a general change of regimen, and the great chancellor is again well and at work.

In conclusion, more attention should be given to hygiene, and less trust put in drugs.

The Hypoglossal Nerve in Connection with Syphilitic Glossoplegia.

The *London Med. Record* tells us that in the Berlin *Charitè Reports*, Band viii., 1883, Lewin treats of the above. Amongst 50,000 cases of syphilis he found nineteen with gummatous glossitis, and three in his private practice, all these twenty-two being affected with paralysis. The histories of two patients are given in full; one suffered from hypoglossal paralysis on one side, with symptoms almost like those of bulbar paralysis, and was cured by sublimate injections. The other presented atrophy of half the tongue, with nodes at its root; deviation of the point to the diseased side (so that it scarcely projected beyond the teeth); failure in raising it to the hard palate; difficulty in masticating, in swallowing, in speaking quickly and for long, and in phonating the letters *d*, *t*, *l*, *n*, *r*. There were also lowered and delayed taste-perception on the left side of tongue; with lowered perception of movement, position, temperature, pain, and electric irritability; salivation, and lastly, a great paleness of that side. *Post mortem*, two gummatous foci were found in the skull; one between the dura mater and the bone to the left of the vertex, the other upon the hypoglossal nerve itself. This nerve, anterior to the condyloid foramen, and partly within it, was embedded in a greyish-white jelly-like gummatous mass. The root-paths of the nerve in the medulla oblongata were unaffected; the trunk alone was involved. A complex of veins existed about the nerve as it entered its canal, like a small cavernous tumor; this evidently arose from the venous circle normally found around the nerve there. The nucleus of origin was normal.

Lewin comments thus upon this case:

1. The *motor paresis* of the tongue was due to the paralysis of its muscles (the genio- and styloglossus, the longitudinal—superior and inferior—and transverse strata, and the genio-hyoid).

2. The *want of taste* is ascribed to pressure by gummata upon the peripheral ends of the glosso-pharyngeal in the circumvallate papillæ. Lewin is thus of opinion that the chorda tympani holds its gustatory fibres only from the glosso-pharyngeus (by the following route: petrosal ganglion, tympanic plexus, small superficial petrosal, otic ganglion).

3. The *salivation* is explained as a reflex act, most probably through the glosso-pharyngeal nerve.

4. The *local anæmia* was the result of compression of the lingual nerve, which, according to Vulpian, holds vaso-dilator nerves for the tongue.

5. The *stuttering or stammering* might be caused either by lessened size of the tongue, or by compression of the fibres of origin of the hypoglossal nerve by the vertebral artery (Willis, "freno injecto circumligans"), or lastly, from pressure of the swollen circulus venosus upon the nerve at the condyloid foramen.

In the historical sketch the various views of the functions of the hypoglossal nerve, from Galen down, are given. Longet says it is only sensitive over the great cornu of the hyoid. Of late years, anatomical search has been made for any nerves which might afford sensory fibres to the hypoglossal. These are detailed thus in the anatomical section. Some authors have thought that the sensory fibres are derived from a small posterior root, provided with a ganglion, like a posterior spinal nerve. Lewin remarks that such a root does not occur in man, and also contends against the view that the superior cervical ganglion sends sensory fibres to the hypoglossus. The anatomical relations of the hypoglossal with the cervical nerves, the vagus, and the lingual nerve are fully detailed.

No satisfactory conclusions from anatomy being

at hand, Dr. Lewin, with Dr. Holtzer, made experiments upon dogs with the following results:

1. The peripheral end of the hypoglossal nerve contains sensory fibres. 2. In most cases these are not derived from the lingual; but (3) arise from fibres accompanying the nerve-trunk. 4. Between the descending branch (descendens noni) and the anastomosis with the lingual, there pass sensory fibres, some from the lingual, others from the hypoglossal. 5. Lingual nerve-fibres descend also in the descendens noni. 6. No sensory fibres pass from the cerebral end of the hypoglossal to the descending branch. 7. Sensory fibres arise in the last-mentioned, apparently from the cervical nerves. 8. Fibres from the lingual nerve (on the distal side of the descendens) run backwards along the hypoglossal to its exit from the condyloid foramen. 9. The hypoglossal itself has no sensibility from its root down. 10. Sensory nerves travel with the hypoglossal (independently of the above-mentioned fibres from nerves elsewhere, by anastomosis) immediately after its exit from the skull; either from the vagus or from the cervical region of the spinal cord.

Sea-sickness.

In the course of an article in the *British Med. Jour.*, July 26, 1884, Dr. Astley Gresswell says:

This complaint varies greatly in degree. Some never suffer from it; they are, however, in a decidedly small minority; some suffer severely at first, but quickly acquire toleration: others apparently never succeed in wholly overcoming the effects of the movement of a ship at sea. We may mention that it occurs in some birds, and is known in many quadrupeds. Most children in health quickly acquire toleration. Women suffer perhaps more generally than men; and it is rare to meet a woman who, though a great traveler by sea, does not suffer severely when a vessel is freely pitching. It is common, also, to meet men who, though great sea-travelers, suffer somewhat when a vessel freely pitches; the customary pipe is not taken, the appetite is in abeyance, and there is a decided preference for the recumbent posture. The suffering is most marked when there are both pitching and rolling, or, as some say, wriggling. The voyager generally quickly becomes adapted to rolling when occurring alone, but not so readily to pitching, which is the movement that longest retains its influence; the symptoms also are the more severe the greater the angle through which the vessel pitches, so that, for instance, the occupants of stern-cabins suffer more than those of cabins amidship; and, moreover, they are more severe when standing than when sitting or lying. Pitching would, by virtue of the law of inertia, cause sudden changes in the amount of fluid contained within the cranium. During the descent there would be some addition to the intracranial fluid-pressure, and during the ascent some reduction of it. In rolling, again, similar alternations of pressure doubtless occur, but they would not be so great, for a ship generally rolls through a much smaller angle than that through which it can pitch.

Pitching would also cause many other changes in the body; it would, for instance, cause sudden slight tractions upon the mesentery, small omentum, and suspensory ligament of the liver, in consequence of the inertia of the small intestines, stomach, and liver; and one may be tempted to suppose that, in this way, pitching may cause reflex vomiting. It would perhaps act similarly upon the aorta, by reason of the inertia of the heart. If, however, pitching cause sudden changes of intracranial fluid-pressure, we might expect to find vomiting associated with it. Anæmia of the brain causes vertigo, nausea, and vomiting. These symptoms are present in cases of hemorrhage; they also occur on suddenly taking the erect posture, and especially is this the case with anæmics and convalescents; a convalescent typhus-patient will sometimes vomit while being helped to sit up in bed; and a patient rendered anæmic by hæmatemesis will very probably vomit if raised, so that, if raised before the vessels have thoroughly healed, the latter may be opened up afresh. Thinking that sudden changes of intracranial fluid pressure had to do with the symptoms of sea-sickness, I tried the administration of ergot and digitalis, hoping, by raising the blood-pressure, to reduce the effect of pitching upon the intracranial fluid. I gave these drugs freely to as many as a hundred and ninety persons suffering from sea-sickness; and, in very many cases, they apparently acted remarkably well, some (especially lads) requiring no more than one or two doses. I should say that chloroform also was almost always given. It may be premature to suggest a *rationale* as to why sudden changes of intracranial fluid should be attended by nausea and vomiting; it may be owing to a disturbance of the coördinate action of the higher cerebral centres, or of the lower more automatic centres; it may be that it acts upon these centres by disturbing the perilymph or the endolymph.

The peculiar sensation in the chest and abdomen when swinging, or at the sudden start or pull up of a railway carriage, may be attributable to change of mutual pressure of parts within the abdomen and chest. Swinging often indeed causes sickness; but the movement of swinging differs greatly from that which is undergone in a ship when freely pitching. In pitching, there may be such sudden change from ascent to descent, that one feels as if left in the air; and, again, such sudden change from descent to ascent, that one feels as if about to pass through the deck. And it is, I think, just this fact of sudden interruption of the movement that constitutes the difficulty to be overcome on a ship; moreover, it is just at these times, and often only at these times, that great sea-travelers experience nausea.

This view of the etiology of sea-sickness may be objected to on the ground that quadrupeds suffer from it. Pitching would, however, act on the intracranial pressure of the quadruped, when standing, in the same direction as, though to a less degree than, it would in the case of man.

Whether, however, the etiology here advanced be correct or not, the drugs above-mentioned seemed to act so well as to justify, I have thought, these few remarks. It may be well to add that some irritants have a marked effect in checking, at any rate, the vomiting of sea-sickness; and of these, the most useful, perhaps, is tincture of capsicum; spiritus ammoniæ aromaticus also is of value.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

ACUTE TRAUMATIC MALIGNANCY.

Some two years ago, we had occasion to call attention to a condition of affairs where, owing to some inherent peculiarity of constitution, some tumor-favoring diathesis, an injury that, under ordinary circumstances, in a healthy person, should heal kindly, will rapidly run into the state of malignant disease.

Mr. Richard Barwell, in his introductory remarks in the paper to which we then alluded, says: "The cases on which the name is founded made a great impression on my mind, leading me to think that occasionally under the stimulus of severe irritation the tissue elements, which under favorable circumstances would assume only the additional activity necessary for repair, may exhibit a more prolific cell-germination, culminating in a rapid form of malignant disease in one of those forms, whether named myeloid or round-celled sarcoma or encephaloid cancer, which consists of little else than heaped-up cells and their progeny."

The fact that such unfortunate and unexpected changes do take place sometimes has been made repeatedly evident to us, and it seems to be a subject well worthy of further investigation and elucidation. Therefore are we pleased to note that in the *Lancet*, July 26, 1884, Dr. Lambert H. Ormsby contributes more information on the subject. Before relating some cases, he gives the results of his experience as follows

"In the following cases it will be found that malignant tendencies rapidly developed after the receipt of local injury. I would, however, be inclined to think that, without some inherent malignant constitutional tendency, a local injury would not be followed by anything more than some slight temporary benign irritation and inflammation necessary for the healthy reparation of the part. For it would appear, according to Billroth, that the development of tumor depends upon two factors: 1. The inherent tumor-forming diathesis. 2. Local irritation, which may be either inflicted suddenly or may be of long-continued duration.

"As already mentioned, in healthy individuals we find local injuries, such as wounds and blows, merely go through the benign and natural processes sufficient for repair, such as inflammation,

ulceration, suppuration, and cicatrization, and such injuries produce no bad constitutional or local effects whatever. On the other hand, in patients with a constitution having a hereditary tendency to tumor diathesis, small skin wounds and other slight injuries are rapidly followed by a very fast-growing malignant tumor at the original seat of injury. From this, then, it would seem that although the tumor diathesis may be present in the body of a given individual, the condition may be harmless for a certain limited time, or for a very considerable period, as it requires another factor to complete the process of malignant development, and such factor, it would appear, is frequently contributed by a traumatism or other local irritation of one kind or another; and should the latter factor of local irritation be wanting, no malignant development takes place.

"Take, for example, the lower lip, a very common situation among certain classes of epithelial cancer to make its appearance. In early stages, and up to a certain point, I would think that only the tumor diathesis was present—in fact, that it was in a pre-malignant condition. To this add the factor of continual local irritation by means of the heated stem of a short clay pipe, and you have epithelial cancer very rapidly developed. Also, in malignant tumors of the breast, the tumor-producing diathesis may be present for a considerable time, and no malignant development take place until a blow or other injury is received at the part, and rapid enlargement and growth follow."

COMMITMENTS TO LUNATIC ASYLUMS.

An important case in England recently brought up for criticism the method of procedure in committing persons to insane asylums, and the judges condemned quite severely the means often taken by interested persons to secure commitments. The suit was against Dr. Forbes Winslow, the alienist, by a Mrs. Weldon, the person whose insanity was alleged. The charges were of assault and battery in attempting to carry out the commitment, and of libel in writing to Mr. Weldon that she was a proper subject for incarceration. The defense interposed by Dr. Winslow was, that he had acted under the lunacy statutes in attempting to take Mrs. Weldon to the asylum, and that he had written the letter as a physician, without malice, and it was therefore a privileged communication.

Dr. Winslow was successful in his defense on the first trial, but this judgment was finally reversed on appeal. It appeared that Dr. Winslow was the proprietor of the private asylum where Mrs. Weldon was to be confined, and he was one of the two physicians who made the examination required by law as to her sanity. The court therefore held, that as he would receive compensation for her confinement, he was interested in giving such a certificate as would enable him to take her to the asylum. He was not, therefore, a disinterested person, and no one should be deprived of liberty where there was any question as to the possible motives. The court did not decide that Dr. Winslow had acted improperly, but that the facts warranted the submission of the case to a jury which had been refused by the trial judge. It also appeared that the method of examination was peculiar and improper. The law required two separate and independent examinations of the patient, but the two physicians who gave the certificate went together to the house, and after having an interview together with her, took turns in stepping out so that each might make what would be called a separate and independent examination.

Under these circumstances it was held that a jury should have decided as to the propriety of the course taken by Dr. Winslow, and as this was not done, the judgment must be reversed.

WHO SHALL PAY PHYSICIANS EMPLOYED TO ATTEND THE POOR?

A physician who renders his services to the public poor, or in any capacity where the compensation is to be paid from the county or city treasury must see to it that his employment is from the proper authorities, or else he can not recover the value of his services. He may act in perfect good faith, but if the appointment is not from the source which the law recognizes, he must secure his pay, if he secures it at all, from the persons who employed him.

This appears from a recent case in Iowa, where the following question was submitted to the court: "When the board of supervisors of a county in

which there is no poor-house, employs a convenient and competent physician to furnish to all the poor persons of the county all medicines and medical aid that such poor persons may require, while such physician is so employed, and ready and able to furnish such medicines and medical aid, may the trustees of the township in which the physician resides disregard such employment made by the board of supervisors, and employ other physicians to furnish medicines and medical aid to the poor persons of said township who make application to them therefor, and bind the county for the payment of medicines and medical services rendered or furnished by such physician employed by the trustees?"

The circumstances of the case show that the Iowa law provides for the care of the sick poor by the trustees of the township until the supervisors provide for such care, but does not make provision for any conflict of authority between the trustees and the board of supervisors. It seemed that the supervisors had a regularly appointed physician, ready to attend to all cases, and the trustees, instead of calling on him, employed another physician, and the latter after rendering the services desired, sued the county for his fees. At the first trial the physician was successful and obtained a verdict; but on appeal, when the above question was submitted to the higher court for decision, it was held that the verdict must be reversed. The ground of the decision was that the township trustees could not bind the county for medical services when there was a regularly appointed physician whom they might employ, but did not want to.

Notes and Comments.

Antipyrin.

The reports concerning the antipyretic effect of antipyrin accumulate, and prove that the remedy does not only cause a decided and prompt reduction of temperature, but has also the great advantage of not being accompanied or followed by any of the disagreeable effects of quinine.

Antipyrin is best administered in hourly doses of 32+32+16 grains, so that within two hours the whole dose of 80 grains is taken. The reduction of temperature varies from 2 to 6 degrees, and sets in gradually. As soon as the effect of antipyrin has ceased, which usually happens within five hours after the last of the three doses mentioned, the temperature continues stationary for an hour or two, and then slowly ascends to its former height, if meanwhile no more doses of antipyrin are administered. In a case of tubercular phthisis, with hectic fever, where the temperature rose every afternoon at three o'clock to 104½°, the first dose of 32 grains of antipyrin was given at 12 m., the second of the same quantity at 1 p. m., and the last of 16 grains one hour later. The temperature at 3 p. m. rose but to 99½°, and continued at that height till 8 p. m., when it again ascended to 100½°. If a fourth dose of 32 grains was administered at 6 p. m., the temperature declined still more, until it reached at 8 p. m. 98°, when it again gradually crept up to 99½°. No nausea and no tinnitus aurium were observed.

Recently Dr. C. Rank reports, that the drug occasionally causes nausea and vomiting, if administered internally (*Allg. Med. Centr. Zeit.*, 52, 1884). He therefore made use of it by the hypodermic method, and found it, in a series of fifty cases, not only to answer admirably well, but to have a still prompter and more decided effect than if given internally, but also never to produce any disagreeable symptoms. As antipyrin dissolves in cold water but sparingly (1 : 3), and as 32 to 64 grains must be injected under the skin to obtain the full antipyretic effect of the drug, Dr. R. made a trial with hot water, and discovered that 16 grains of antipyrin dissolves in 8 minims of hot water, and that the remedy does not precipitate when the solution has cooled down. After having been kept in a room for a period of eight days, this solution was still clear. One or one and a half syringefuls of it suffices to produce the antipyretic effect of antipyrin.

The injections were usually made in the region of the glutæus muscles, and with the exception of a very slight and transient pain, no local symptoms showed themselves at the place of injection, no inflammation, hardening or formation of pus. Where internally, eighty grains are necessary (32+32+16 grains administered hourly), R. succeeded with one hypodermic dose of one, or at most one and a half syringefuls of his solution. According to his experience, the maximum of decline of temperature happens about three hours after the injection, and continues from six to eight hours.

It is well known that with one or two doses of sulphate or muriate of quinine, of thirty grains each, we may obtain a similar antipyretic effect; but quinine has the drawback in such doses generally of inducing vomiting, and often tinnitus aurium, besides producing not seldom other more dangerous symptoms due to congestion of the brain. That antipyrin, while possessing, if possible, a still prompter antipyretic effect—more decided and more lasting—has none of these disagreeable symptoms, makes this drug so valuable. To these facts may be added, as of not less importance, the facility with which antipyrin can be subcutaneously employed. Lastly, it is but half as dear as quinine.

The Treatment of Pernicious Intermittent Fever.

Dr. W. H. Reed reports an interesting case, which yielded to treatment, in the *College and Clinical Record*, August 1, 1884:

His treatment was as follows: Immediately a hypodermic injection of one-sixth grain of morphiæ sulph.; hot sand-bag to lumbar region; one pil. podophyllin comp., and two grains of quiniæ sulph., in pills, every two hours, until twenty grains were taken. He was sent for hurriedly, with the statement that his patient was dying. On his arrival by her bedside, he found her in a sinking condition; in the meantime she had had several convulsions; was now at times in a low delirium, muttering inaudible and unconnected sentences, and picking at the bed-clothes. Her countenance was relaxed, tired, worn, and haggard; skin somewhat cooler, and pulse almost imperceptible; heart sounds feeble; respiration slow and gasping. The pain had left the back, from the application of the sand-bag. He immediately stimulated her freely with whiskey, which at first produced retching, but not vomiting; then he was informed that on two occasions previously she had vomited blood. He ordered dry heat over her stomach, which successfully allayed further vomiting and retching, thereby enabling her to retain all medicine administered. A strong milk punch was given at intervals during the night, and the quinine pills continued as before ordered. Next day he found his patient much improved; she was lying quietly in bed, her mind clear and buoyant, but she was much exhausted and debilitated. The delirium passed off about midnight, and her bowels moved freely toward morning. Her skin was almost normal in temperature, and but slightly jaundiced; heart sounds regular, but slightly feeble; respiration normal; no thirst; tongue coated with a rather heavy fur; she ate some prepared gluten and milk for breakfast. He prescribed—

℞. Hydrargyri chloridi mitis, gr. ij.
Pulv. ipecac., gr. ij.
Pulv. ingluvin, ʒj. M.
Fiant chartæ viij.
Sig.—One to be taken every two hours.

He also gave her ten-drop doses of Fowler's solution three times a day. When he saw her again two days later, his patient was out of bed, with skin comparatively clear; appetite returned, and she was commencing to feel strong again. At the septenary periods he prescribed twenty-four grains of cinchoniæ sulphas. One week later he diminished the Fowler's solution to five drops three times a day. Two weeks later he saw his patient; she was feeling exceedingly well, with no symptoms of a recurrence of the chill.

Regulation of Diet.

As illustrating the great importance of this all-important question, we are glad to quote the following remarks from Dr. R. H. Gunning (*Edinburgh Medical Journal*, June, 1884):

The function which influences all others most is digestion. This all right, all is right, and *vice versa*. Cures, after operations, are accomplished by nutrition; and this will be good, or the contrary, as the digestion is good or the contrary. This subject of digestion and nutrition should be well understood by surgeons. The preparing a patient for an operation, or treating him after, hang much on this. Whatever dexterity a surgeon may have, he should also understand physiology well to have success. He may fail sometimes from neglect of the simplest dogmas of physiology. A friend and myself, when abroad, had many cases of cataract. We did the operation in the same way; he better than I, for I had no gift of hands. He lost very many of his cases, and mine succeeded. He said, one day, he could not understand this. I replied, "It is simple; you let your patients *eat and drink* as they and friends like after the operation; while I starve mine for one or two days, till the wound is healed and the retina is safe." A full stomach or improper food will soon befool the best-done operation. I have cured serious fractures without fever intervening merely by semi-starving the patient. In my own case, when shot in the head, I abstained from all but water, or a little tea or dry toast, for days, and had scarcely pain and no fever or erysipelas. After days I used stewed prunes, potatoes mashed with salt butter, to be simple and laxative. I took no wine and no

meat for weeks, and a remarkable cure was the result.

In all cases, medical or surgical, attention must be given to the digestive organs, to see that no peccant or irritating matter exists, and that they be carefully watched afterwards.

I once treated a lad for fracture of both thigh bones, a bullock-car having passed over his limbs. I set the limbs, and kept him semi-starved for days. Only gruel or weak chicken broth was allowed. He had no fever, and got round beautifully. On another occasion the car passed over him and killed him. In short, let all ingesta be in the smallest quantity, and of mild quality, to avoid inflammation. Spirits in every shape are injurious.

Phosphorus in Craniotabes.

That phosphorus, administered internally, greatly influences the nutrition and the growth of bones, has been conclusively proven. This remedy would find, therefore, its main indication in those diseases of the bones due to malnutrition, and specially frequent in childhood. But considering the poisonous action of the drug, and its great danger in children, Dr. Fred. Betz, in Heilbronn (Memorabilien, 4 Heft, 1884), resolved to try its local application. There was one other reason inducing him in children to discard the internal use of phosphorus; that was the fact that we do not possess any criterion by which we might recognize the limits of physiological poisoning, as the œdema of the eyelids, the ophthalmia, the gastric pain, and the diarrhœa, are the warning symptoms, for instance, in arsenious acid.

To a number of children suffering from craniotabes B. applied a salve of phosphorus, rubbing it into the integument of the head. "The results," says he, "were more striking than those following Karsowitz's internal medication. The softness of the occipital bone ceased after a few weeks; the sutures became more prominent, and the fontanelles smaller, while the size of the head greatly diminished. Another remarkable phenomenon was the luxuriant growth of the hair, which not only became denser and longer, but also thicker. The children lost their restlessness, their insomnia and psychical excitement. Two children, that were besides affected with laryngismus stridulus, became quieter and livelier, and the seizures ceased."

In conclusion, B. recommends the local application of phosphorus in the very beginning of the disease, while he does not think so well of its efficacy in general rachitis, though being certain of its absorption by the skin. We ourselves have considerable doubt regarding the correctness of Betz's observations, for such cases often spontaneously improve—*vix medicatrix naturæ*. Still it can do no harm to try the local application of phosphorus in the cases indicated. A series of experiments instituted by those that have plenty of such cases under their charge, and made with the view of determining the effect of the treatment, would soon decide its usefulness or uselessness.

Chorea as a Complication of Pleurisy.

Several cases have been reported where after intra-pleural injections for empyema, fatal epileptiform seizures have occurred. From an English exchange we note that the subject has again been brought under notice by Dr. Weill, of Lyons, who records a case where hemi-chorea was apparently excited in the same way (*Revue de Médecine*, July, 1884). A young man, twenty-four years of age, whilst on military service, was attacked with left-sided pleurisy, for which paracentesis was performed. Empyema followed, necessitating drainage and injections, and it was noticed that the left arm became weak immediately after the operation. A year later a second operation was performed, and six months afterwards M. Lépine, under whose care the patient was, deemed it necessary to have portions of the second, third, fourth, and fifth ribs resected. Two days after this operation the left upper limb became the seat of involuntary movements, and shortly after the left lower limb also. These movements were of a choreic character, and were associated with some hyperæsthesia of the hand and a certain degree of ataxy in the lower limb. The condition was attributed to the pleural irritation produced by the antiseptic injections acting on the spinal cord, and thence affecting in a reflex way the limbs of the same side. This idea of reflex irritation proposed by M. Lépine seems to M. Weill a very reasonable hypothesis, and it would appear as if there were functional and pathological connections between the innervation of the pleura and that of the limbs of the same side, especially of the upper limb. The occurrence of radiating pain in angina pectoris, and of the shoulder pain in hepatic colic, are instances of a similar kind; and the fact that besides the severe and fatal convulsions excited by intra-pleural injections, there have also been recorded numerous instances of hemiplegia associated with like pleural conditions, justifies the notion that in the present case there is an example of chorea excited by the same path.

Veratrum Viride in Puerperal Eclampsia.

Of the various remedies recommended for this disease, we would certainly imagine, reasoning theoretically that veratrum viride was the most dangerous. But Dr. H. W. Brown writes to the *Obstetric Gaz.*, July, 1884, that although he has only used it in six cases, yet he feels sure that these cases prove the efficiency of the remedy, and show that the fears entertained by the profession as to its deadly poisonous effects when given in large doses are unfounded. We will give one of his six cases as illustrating his method of administration:

"March 10, 1884, I was called to Lynchburg, Ohio, by Mr. L., to see his wife in puerperal convulsions. His first wife had died two or three years previous of the same disease, under the chloroform and morphia treatment. As a matter of course, the family were very much alarmed at the second case. When I arrived, I found the case in charge of Drs. Kleckner, of Lynchburg, and Marsh, of Dodsonville. She had had some three or four convulsions, and was very restless and nervous, barely comprehending anything that was said to her. She had been in labor five or six hours, with no progress. The os was not dilated at all, but pains were severe. I recommended ninety drops of Norwood's tincture, which was given under protest by Dr. Kleckner. This was repeated at intervals of thirty minutes, only in smaller doses (about sixty drops each time), until we gave four or five doses, when she vomited and was thoroughly relaxed. In our anxiety concerning the convulsions, we had forgotten to ascertain whether or not the os was dilated. I made an examination, and, to my surprise, the head was presenting in first position low down. We delivered immediately, and our patient went off to sleep with pulse down to fifty. She needed no more treatment, and is well and hearty now.

Algid Collapse.

In *La France Med.*, Hallopeau, under the name of algid collapse, describes a condition characterized by partial or general coldness of the body, accompanied with prostration. He regards the condition as the opposite of what occurs in fevers, and that it is due to an opposite state of the vasomotor nerves to that which is present in fever. The condition is specially observed in cases where the abdominal viscera are the seat of violent irritation, as in cholera, irritant poisoning, intestinal strangulation, and injuries to the abdomen. The lowering of the temperature usually begins in the extremities and face, and may be confined to these parts, but may become general. The contraction of the capillaries in these parts, and the consequent diminution in the amount of heat thus lost, would lead to the expectation that the internal temperature would be raised, which is not generally found to be the case, and this is explained on the supposition that there is a concomitant diminution in the activity of combustion. The pulse is small; the heart sounds are very feeble. The integuments are pale or cyanotic, and covered with a cold perspiration. There is often a degree of dyspnœa not explicable by respiratory lesion. The urine is diminished, and is often albuminous. There are muscular cramps; and the patient suffers from vertigo. He holds that the condition is due to the irritation of the sympathetic centre by the nerves going from the affected part, and through the sympathetic the calibre of the arteries is diminished; that by this means there is venous engorgement and deficient oxidation in the lungs, etc. He believes the condition is not to be explained by a general affection of the circulation, but is due to local disturbances in the circulation and the *calorification;* and this, he thinks, is proved by the symptoms of the collapse being limited to certain parts, particularly the face and extremities.

Hyperosmic Acid in Neuralgia.

In Tübingen, as well as in Kiel, experiments have recently been made to determine the action of hyperosmic acid (*Deutsch Med. Zeit.*, July 7, 1884). This drug was first recommended in malignant tumors, into whose parenchyma the acid was injected. In both localities the result has been nihil, the inflammation ensuing exerting no influence on the malignant character of the new growth. As well known, Dr. Winiwarter was the first to bring the remedy to the notice of the profession.

Dr. Neuber, in Kiel, accidentally employed the hyperosmic acid in several cases of peripheral neuralgia, which had not yielded to other drugs. He reports three cases where a daily subcutaneous injection of the acid was employed. He made use of a one per cent. watery solution, of which from four to six drops sufficed for each injection. Selecting the locality most affected by the pain for the hypodermic application of hyperosmic acid he found that in each of the three cases of neuralgia, though they were of stubborn character and had thus far withstood every possible treatment, the effect of the acid was magical, the pain after a few applications ceasing, and in no instance returning. The injections themselves were

neither very painful, nor followed by suppuration, nor accompanied by poisonous side effects.

There are many cases of superficial neuralgia which apparently are incurable until some new remedy is tried, to which they at once yield. The more physicians report such cases, the sooner will the conditions be determined, under which each anti-neuralgic remedy may be expected to act promptly.

Trephining on Account of Necrosis.

A boy, æt. 15, was said to have suffered in May, 1882, from typhoid fever. Soon after, a swelling was noticed in the left occipital region. July of the same year, an abscess developed itself in the same place, and was opened. December 6, the patient entered the hospital of Dr. A. Kine, in Moskow (Lyctopissj chirurg. Obschtschestwa w Moskwe, 7, '83, Russ.). K. discovered at the border between the left temporal and the occipital bone a fistula, sounding which he felt the bone denuded of its periosteum, and at the same time observed a pulsatory motion of the pus at the bottom of the fistula.

The abscess cavity was laid open, when there appeared a necrotic piece of bone of the size of a silver dollar, showing in its centre a perforated place as large as a pea, through which the dura mater could be seen, also covered by a caseous formation. K. made the diagnosis of tubercular ulceration of the occipital bone, and determined to perform trephining. The whole piece of necrotic bone was removed with the chisel, also a piece of the dura mater. Drainage was established and a Lister-bandage applied. Cure by first intention took place, except at the opening for drainage, where again a fistula formed, which did not close until September, 1883. The cicatrix consists only of dense areolar tissue, dense and strong enough, however, to serve as a bony covering. No hair has grown at the place.

The patient was presented cured to the Surgical Society of Moscow.

The Transmissibility of Bovine Tuberculosis Through Milk to Young Animals.

This subject, which has been receiving considerable attention lately, is discussed by Dr. Francis Imlach in the *British Medical Journal*, July 26, 1884, who concludes from his experiments that healthy young animals carefully selected and tended, may be safely fed with the milk of tuberculous cows without the rapid development of tuberculosis. Only in two monkeys was there evidence of tubercle, and the disease is too common amongst them in England to allow us to ascribe its development to infection by milk. Of the ultimate results of such feeding it would be unsafe to make any assertion, for extensive observations would be necessary in order to avoid numerous obvious fallacies. The investigations carried on in Berlin under the superintendence of Virchow having left this question unsettled, it would be a great boon to the medical profession if Mr. George Fleming, who has so ably and so forcibly drawn attention to it, or some other veterinary authority with facilities and skill superior to what any member of our profession can be expected to have, would subject this great problem to a practical test.

In Vienna, New York, and elsewhere, efforts have recently been made to suppress the sale of milk from tuberculous cows by legal enactment. Though the observations above recorded do not suggest that a healthy child in a comfortable home would be hurt by the occasional ingestion of such milk, it would be rash to conclude, without further observations, that tubercle might not thus be engendered in an ill-fed and ill-clad child, with an unhealthy heritage and a digestive mucous membrane eroded by frequent diarrhœa.

Hypo-nitrous Acid a Remedy in Cholera.

Dr. Roman de Luna has published the following observations (Arch. d. Pharm., June, 1884,) which he made during the epidemic of Asiatic cholera in Madrid, and last year in Manila.

The infectious element of cholera contaminates the atmosphere, and thus infects persons and inanimate objects. The infection takes place solely by the respiratory passages, and especially during the period of rest, *i. e.*, while the individuals are asleep. The microbe acts mainly on the blood corpuscles, prevents the formation of blood, and thus causes a kind of suffocation, at last ending in death. The sole remedy for cholera patients in the cold stage consists in the inspiration of air, which is cautiously mixed with the vapor of nitrous acid (subnitric acid—unter salpeter säure).

In the cases reported by L., two or three inhalations generally sufficed to produce a great amelioration of the threatening symptoms and to induce reaction, and a few hours later the patients were free from danger. As a preventive remedy, L. recommends, therefore, the fumigation of inhabited rooms twice daily, every morning and night. During the terrible epidemic of Asiatic cholera in Manila last year, of the 300 men working in the mint of Manila and exposed to the influence of nitrous acid vapors not a single one be-

came affected with cholera—a fact which, considering the spread of the disease in that locality, would, if true, be almost convincing of the preventive and curative action of nitrous acid.

Calculus in a Boy Aged Five Years.

To a recent meeting of the Medico-Chirurgical Society of Edinburgh, Prof. Chiene showed a calculus from a boy aged five years, who had been sent by Dr. Hutchinson, of Cockermouth, with the history that he had very frequently to make water during the day and night. On November 14 of last year, under chloroform, a small sound was with difficulty passed into the bladder. A grating sensation was felt as it passed through the membranous urethra. No stone could be detected in the bladder; but by the rectum a stone was felt lying in the membranous urethra. A staff was then passed as far as the calculus, an incision was made in the raphe of the perineum, and the membranous urethra opened into. An attempt was then made, with the finger in the rectum, to push the stone out of the wound, but it now slipped back into the bladder. An incision was then made through the prostate, and the stone was removed. The thicker end of the stone was in the bladder, the other end forming a mould of the membranous portion of the urethra.

Fœtal Movements in the Diagnosis of Pregnancy.

Dr. Theophilus Parvin (*College and Clinical Record*, August 1, 1884,) says that they must be movements which you see or feel, not that you are told of, in order to have any value. Now it is generally easy if these movements do not occur spontaneously in the course of your examination by palpation and auscultation, to cause them. The fœtal ovoid is adapted, accommodated, to the uterine ovoidal cavity. Change the shape of that cavity by pressing the hand firmly upon the uterus, so that the accommodation is, for the time being, lost, and the fœtus moves for the purpose of restoring it. He thinks very probably this pressure has made the fœtus uncomfortable, and it moves to find a comfortable position. Uterine contractions may be excited by this pressure, and fœtal movements follow them. The one word which explains the position which the fœtus occupies in the womb, and the most important of the mechanical phenomena of labor, is the word *accommodation*.

"Take your Forceps with You."

Dr. H. V. Sweringen, of Fort Wayne, Ind. (who is well-known to our readers), contributes an article with this caption to the July number of the *Obstetric Gazette*, for the purpose of warning all physicians to be very particular always to carry with them to every labor case their forceps. It is well to issue such a warning occasionally, because on account of the very large proportion of cases of parturition that terminate spontaneously, the physician is very apt to leave his forceps at home, feeling that the chances are against his being obliged to use them, and if his home is far from his patient, and the demand for instrumental interference becomes very urgent, the patient may die before the forceps can be procured. Such a case has happened to Dr. S., and he concludes his article by saying, "I verily believe, that if she had been delivered *promptly*, with the forceps, immediately upon or before the appearance of her first convulsion, her life would have been saved. I close as I began, *take your forceps with you always.*"

Treatment of Nasal Polypi.

As a valuable contribution to the therapeutics of this unpleasant condition, we are glad to note that Dr. Richardson, in the *Asclepiad*, recommends the use of sodium ethylate in the treatment of nasal polypus. The caustic agent is applied by means of a probe made of soft cotton-wool, twisted into shape on the points of a pair of forceps. This cotton probe is saturated with the ethylate, and then plunged into the substance of the polypus. On removing the cotton it commonly happens that the patient can expel the whole mass of destroyed polypus, in a semi-fluid form, by blowing the nose sharply. A second application ought to be made with a view of destroying the base of the polypus. The mode of action is said to be sufficiently clear. The ethylate is decomposed by contact with the water of the polypus into caustic soda and alcohol; the latter coagulates the albuminoids, and the former acts as a powerful caustic. With the exception of some burning pain, no unpleasant effects seem to follow the use of this method.

Cold Ablutions of the Feet for Cold in the Head.

The following simple measure is highly recommended by Dr. Prokop Popoff, of Siberia, who states in the *Russkaia Meditz* that in more than 300 cases of acute and chronic rheumatic coryza he used it with great success: Twice daily (in the morning on rising, and at night on going to bed) for two days the patients are ordered to wash their legs from the sole up to the knee with ice-cold water, and to subsequently rub the washed parts with a dry towel, or a piece of rough linen

or cloth, until a vivid redness and feeling of warmth appears. The whole procedure takes not more than five minutes. No other measures or precautions are required. A striking improvement follows already on the next day; in fact, the improvement is usually so great, that many patients content themselves only with one day's treatment, regarding themselves as cured.

Bacterial Urethritis.

From the *Lancet* we note that the number of varieties of inflammation of the urethra cannot properly be regarded as less than the number of inflammations of any other mucous surface. It has long been recognized by surgeons that intense urethritis is not necessarily of gonorrhœal nature. Neisser and others have described a micrococcus as the cause of gonorrhœa. Aubert has for some time past made a systematic examination of urethral discharges, and in three instances has found, instead of gonococcus, a rod-shaped microorganism. He has traced a resemblance between these bacteria and those found in pus from ulcerative balanitis. Although Aubert is inclined to regard the presence of the bacilli as indicating a different variety of urethritis, he wisely abstains from giving his positive adhesion to this view.

Injury of the Head, followed by Temporary Blindness and Anosmia.

Before the Ophthalmological Society of Great Britain (July 4, 1884), Mr. Spencer Watson reported the case of a man who threw himself out of a window a height of forty feet from the ground, and was taken up in an unconscious state. He regained partial consciousness, and then became violently delirious. After the swelling of the eyelids had passed off, he was found to be absolutely blind, and ophthalmoscopic examination revealed engorged optic discs. Loss of smell was also noticed at this time. In a few days the sight improved, and at the end of six weeks was quite restored. The anosmia, however, remained. The probable cause of these losses of sensory activity was a hemorrhage in the middle and anterior fossæ.

Pathology of Miliary Tuberculosis.

Careful observations have proven that the introduction of any poisonous material in the blood, and acting as a foreign body in the tissues, (as mercury, etc.), is always deposited in the parenchyma of organs, in the form of tubercles, being small emboli. Dr. C. Benda, at the last meeting of the Berlin Physiological Institute, demonstrated that tubercle-bacilli, if forced into the circulation of animals, was carried along until they reached the capillary vessels in the tissues, where they were deposited like emboli. We have thus an explanation why in miliary tuberculosis so many different foci are found in various organs. The further our investigations progress, the more certain appear the microzymes as pathogenic elements of infectious diseases.

Pruritus Vaginæ.

Dr. Hach stated at the Riga Medical Society (*St. Petersburger Medicinische Wochenschrift*, March 22), that, in a very obstinate case, in which various external and internal means had been employed in vain, he had met with complete success from dusting the mucous membrane of the vagina with iodoform. Beyond slight redness of the vagina, no diseased appearances were observable. Dr. Rulle stated that he had often employed iodoform balls in this affection, but had derived better results from the watery extract of opium, and small injections of cold water. He believed that this pruritus often arose from a slight dilatation of the rectum, just above the sphincter ani, which gave rise to detention of fæces there.

Correspondence.

A Case of Alopecia Areata.

Eds. Med. and Surgical Reporter:

There has lately come under my notice a rather severe case of this rare disease; and inasmuch as it may present some features that will bear on the etiology of this affection, I thought it would be well to report it.

A man, aged about 40, of full, plethoric habit, while talking to me one day, removed his hat, and said, "Doctor, what do you call that?" His scalp was perfectly destitute of hair in any shape or form. Upon further observation, I found that the *whole body*, including eyebrows, eyelids, face, axillæ, and pubes, was in the same condition. He remarked: "One year ago the first of last May, I was as hairy a man as you would see anywhere, with a full beard that reached to my waist." If there is a single hair on his body now, I failed to find it. The history is this:

For several years he has been afflicted with supra-orbital and occipital neuralgia, as well as an occasional spell of lumbago. He absolutely denies syphilis, and I have every reason to believe that he has never had it, not being able to find any indication of it in any part of the body. His general health is good. Has never had any severe sickness; and I might say has had no sickness at all, having been strong and hearty all his life. He has never had any skin disease in his life, except scabies when a boy. The present difficulty dates from sometime in May, 1883. It commenced by the falling out of spots of hair,

first on the temples, and gradually passing around to the occipital region; then commencing on the brow and passing backward to complete the scalp; then the eyebrows and eyelashes, the whiskers, and finally that on the rest of the body.

This all occurred inside of three months. After the hair had fallen out, lanugines appeared, but also dropped out quickly. He has been treated by many of the best-read physicians of this vicinity, mostly upon the anti-parasitic plan, but all treatment has absolutely failed.

The conclusions I draw from this case, and the result of treatment, are:

1. The possibility of its origin being a nerve disturbance, causing impaired nutrition; and,
2. That it is not parasitic.

George A. Stuart, M. D.,

News and Miscellany.

Incidents in the Life of a Great Man.

As serving to set a good example for us all to follow, from the *Scientific American* we note that in a memorial sketch contributed to the New York *Medical Journal* by Dr. W. Gill Wylie, on the life and works of the late Doctor J. Marion Sims, many interesting facts and incidents in his life are given. We omit what the writer says of Doctor Sims' professional work, and confine our extracts to the biographer's testimonial of his deceased friend's personal habits and methods, which carry with them a good example for others to follow:

"He was truly master of himself. Vices he had none, not even of the smallest kind. The animal in him was completely under control. His habits and his appetites were always guided by his reason. I have known him, day after day, and month after month, rise at seven, take a simple breakfast, consisting of a glass of milk and Southern hominy, bread and butter, and sometimes an egg. At eight enter his carriage, and make a few morning calls on severe cases. At nine return to his office and see patients till one or one thirty, take a simple lunch of steak, potatoes, etc. At two enter his carriage, visit patients, operate, etc., returning home usually about five or six, write letters, and at seven take a plain dinner of one kind of meat and vegetables. He never took wine, nor coffee, nor tea, nor condiments of any kind. At the table he was usually talkative and playful, talking about the topics of the day, the theatre, of which he was very fond, etc. After dinner he usually wrote letters and did light work, reading journals, etc., or passed his time with his family or friends in the drawing-room. About nine thirty he would usually go to his bedroom, where he read or wrote, sometimes lying in bed until midnight, when he would retire for the night. It was always marvelous to see him so continuously and persistently intent upon his work. He had a habit of writing down ideas at night, by means of a pamphlet, the edge being placed on paper so as to guide his pencil without a light.

"When one was familiar with his capacity for endurance, his power for concentration, his unbounded enthusiasm, his deliberate, persistent, painstaking work, backed up by his unselfishness and undaunted moral courage, it was not surprising to witness his success. His motto as a boy was: 'Duty before pleasure.' Later in life, he needed no motto; it had become a habit for him to do what he thought was right. Difficulties, obstacles, and troubles were as nothing to him when once he had made up his mind to act. He went directly at a thing, and he kept at it until it was mastered. It was this great painstaking and persistent work that made things so clear and so definite to him, and enabled him to express his ideas so lucidly. It was also this power that developed his self-reliance and his moral courage, and made his instruments and his methods of operating so near perfect, that those who claim to improve or to modify them, are merely working backward over the same ground that Marion Sims traveled over in perfecting them. His was the inductive method, or working and perfecting method—a developing method. He cleared away complications, and gradually simplified ideas and instruments, till they approximated the truth and the best.

"He was no idle dreamer; he never wandered into intangible mysticism; there was neither confusion about his work, nor indefiniteness about his aims.

"His mind was always aggressive, progressive, receptive, and ingenious. He was a leader—*a practical genius.*"

The Lithophone.

Mr. James M'Kenzie Davidson, with the assistance of Professor Alex. Ogston, of Aberdeen, has invented and described in the *Lancet* a new instrument which is termed a "lithophone," and is to enable surgeons to hear a stone in the bladder. The instrument is a common sound so arranged at the handle as to admit one end of an elastic tube, the other end of which is inserted into the operator's ear. Prof. Ogston and Mr. Davidson have employed their "lithophone" in clinical teaching, and found it very useful. But we think (says the *Edinburgh Medical Journal*), notwithstanding all they say in praise of their instrument, that the method long ago introduced and used by the late Mr. Spence, of placing a thin, round, flat board on the handle of the sound, is better. By this method the presence of a stone in the bladder can be made distinctly audible to the operator and to a number of bystanders at the same time. Prof. Ogston recommends the "lithophone" as simple and convenient. Mr. Spence's sounding board is both simpler and more convenient. Professor Ogston mentions a case in which the "lithophone" was useful in discovering a stone in the bladder. The calculus, when subsequently caught in a lithotrite, was found to be nearly half an inch in diameter. We humbly submit that such a calculus ought to have been readily felt.

The Habits of an Ovariotomist.

Dr. R. Stansbury Sutton, of Pittsburgh, Pa., who reports ten abdominal sections, with nine recoveries, in the *Obstetric Gazette*, July, 1884, concludes his article by saying: "In all my opera-

tions I have but one assistant, and permit but few spectators. I am not mixed up in general practice, neither is my present assistant, Dr. Stone. My former assistant, Dr. Rahouser, very superior in such work, has kindly stood aside on account of his general practice. Zymotic disease practice and abdominal surgery in my judgment are not compatible. My building has proved too small for abdominal and pelvic surgery. That I might indulge in cervical and perineal surgery, as well as in the less profitable abdominal work, I have erected a separate building on my lot, over one hundred feet from the present building. This new building is especially adapted for abdominal work, and will be used exclusively for this purpose."

Items.

—In the *London Med. Times*, July 26, 1884, Dr. R. Clement Lucas reports a case of peri-nephritic abscess cured by drainage.

—Upwards of one and a half million have visited the International Health Exhibition during the two months it has been open to the public.

—In the *London Med. Times*, July 26, 1884, Dr. C. J. Krickenbeck reports a case of gunshot wound of the colon and base of left lung, with recovery.

—In the *College and Clinical Record*, August 1, 1884, Dr. Lloyd Norris Horwiz reports an interesting case of carcinoma of the pancreas, with secondary involvement of the liver and stomach.

—Moreau de Tours, the celebrated French alienist, whose aphorism, "Le genie est une névrose," made the groundwork of his great work on La Psychologie Morbide, is dead at the age of eighty.

—An apparently authentic account is given of the birth of four living male children by a woman named Mrs. H. W. Pullman, who resides near Eureka, Mo. The mother had previously given birth to triplets.

—Mrs. Juggins: "I always have said it, and says it again—nobody need be ashamed of their origin." Mrs. Muggins: "Jest so, my dear; a little drop in moderation is as good as medicine, and there's nothink orrid about it."

—The Hospital of Jesus, in the city of Mexico, is said to have been founded and endowed by the conqueror Cortez. The government has recently confiscated the property, on the plea that the terms of the founder's will had not been complied with.

—The Emperor of Austria has just conferred upon Hofrath Dr. Carl Langer, Professor of Anatomy in the University of Vienna, the *Ritterkreuz* of the Order of Leopold. This high distinction, in acknowledgment of the merits of this learned savant, indefatigable teacher, and able referee of the Minister of Public Instruction, has given great satisfaction in professional circles.

—Dr. Roussell, the inventor of direct transfusion, has, we are informed from Paris, resumed his former experiments on the hypodermic injection of the salts of copper, which he regards as a prophylactic against cholera. He has also constructed a new apparatus by means of which large quantities of albuminous fluids may be applied hypodermically in the algid stage of cholera.

—On Tuesday, Dr. John S. Billings, of the army, tendered to the International Medical Congress, in session at Copenhagen, an invitation to hold its meeting of 1887 in Washington.

OBITUARY NOTICES.

JOSEPH J. WOODWARD, M. D., U. S. A.

Dr. Joseph J. Woodward, Surgeon U. S. A., died August 17th, near this city. He was born in Philadelphia about 1832, and graduated in medicine from the University of Pennsylvania in 1853. After remaining a short time in private practice in this city, he entered the army, where his valuable labors in connection with the Medical History of the War and the organization of the Army Medical Museum, together with his numerous contributions to our science and literature, have given him wide-spread reputation. Two years ago he was elected president of the American Medical Association, but owing to ill health, on account of which he went abroad, he was unable to take his seat.

DR. C. W. CHAMBERLAIN.

Dr. Charles Walter Chamberlain, Secretary of the State Board of Health of Connecticut, and a member of the National Board of Health, died in Hartford, August 21. Dr. Chamberlain was born in Providence, R. I., July 22, 1844, and was a son of the Rev. Charles Chamberlain. He was educated at Brown University and the College of Physicians and Surgeons in this city, graduating from the latter institution in 1871. He made a specialty of laryngology, and established himself in Hartford. He was Secretary of the State Medical Society in 1876, and contributed to the transactions of that year two papers upon throat diseases, and in the following year a third paper on a similar subject. In 1877, Gov. Hubbard appointed Dr. Chamberlain Examining Surgeon for the soldiers in the State Hospitals. He was also for a number of years Examining Surgeon to the United States Pension Bureau, and was well known throughout the country as a distinguished sanitarian.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

Please answer the following ethical question: The family physician is out of town. Another physician is called to attend a member of the family. While in discharge of this duty, the lady of the house is about to be confined. He is requested to visit her room, remains with her a couple of hours, when the family physician returns. Now, whose patient is it? Should not the physician called surrender the case? What fee is he entitled to? Was he right in remaining through the confinement, then letting the family physician give her subsequent attention, and charging full fee, while the family physician received nothing? I have consulted several of our oldest physicians, and they think he acted wrongly. E. W. C.

Maryland, August 20, 1884.

Ans.—We agree with the opinion of your oldest physicians. EDS. MED. AND SURG. REPORTER.

P. W. V. desires to know which of the sulphur springs is best for a dyspeptic who is troubled with flatulency, constipation, and piles. The White Sulphur in Virginia has been tried, but found to contain too much *gas*.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

SOME OBSERVATIONS ON THE TREATMENT OF COMPOUND FRACTURES OF LONG BONES.

BY J. H. WOODWARD, M. D.

(*Concluded from page* 229.)

Having finished these preliminaries, the surgeon should scrub the injured limb with a brush and soap-suds. This cleansing should be very thorough. The wound-region should then be thoroughly washed with sulphuric ether. Finally, wash the same part with a saturated aqueous solution ($\frac{1}{20}$) of carbolic acid. A solution of corrosive sublimate ($\frac{1}{1000}$) may be used for the same purpose. Constant irrigation of the wound and its vicinity with $\frac{1}{1000}$ corrosive sublimate solution should be commenced at this stage, and continued until the surgeon is ready to apply the dressing. Two assistants should be at hand to keep the limb perfectly quiet during all manipulation of the wound. It goes without saying, of course, that as little unnecessary movement of the fragments as possible should be permitted.

You are now ready to make a careful examination of the case. You study every feature of it, and weigh everything, something after the manner previously sketched. A disinfected finger should be passed into every part of the wound to examine the fragments, to ascertain whether the bones are comminuted, the character of the deformity, the condition of the periosteum, the extent of the laceration, the condition of the arteries—in fact to ascertain the condition of everything in that region of the body. Should you decide to be conservative in your treatment, the hints that will be given as we proceed may prove to be satisfactory guides to the fortunate recovery of the patient. They are offered as the outcome of observations extending through a considerable period of time, made both upon cases that were in our own wards, and also upon those under the care of other surgeons connected with Bellevue Hospital.

The wound should be cleansed of dirt, loose bone-etc., and washed again and again with $\frac{1}{1000}$ solu, tion of corrosive sublimate. The solution should be forced with a syringe into every crevice between the fragments, into every cranny of the wound. Sometimes it will be necessary to enlarge the original wound in order to accomplish thorough disinfection. No surgeon should hesitate to cut as extensively as necessary. Then reduce the deformity perfectly, if possible, and direct the assistants to maintain the fragments in good position, observing at the same time the degree of muscular tension in the limb. If the deformity be readily reproduced when the traction is discontinued, it will be difficult indeed to apply splints in such a manner that they will perform their function. That is true especially in cases of oblique fracture of the bones of the leg and arm. In such cases, it is best to suture the fragments with two or more silver wires. That operation should be done with care, lest the periosteum be unnecessarily injured. The silver sutures may be cut short to remain permanently in the wound, or they may be cut so long that the twisted portion may project through the skin. I have not seen an instance in which silver sutures have done the patient the least harm, and I know that

they have often assisted materially in the cure of the case. In compound fractures of the humerus, when there is much difficulty experienced in maintaining the fragments in good position, the silver suture should be used invariably. I shall not soon forget one such case which was not operated upon, although the indications were clear enough. The wound healed remarkably well, the patient did not have a rise of temperature higher than 99½°; but the result was anything but flattering. For the fracture did not unite, and anchylosis, that, under the circumstances, could not be prevented, became so marked that the patient's whole extremity is absolutely worthless. I am thoroughly convinced that the disastrous result was owing to the failure to wire the fragments together.

Frequently, counter-openings should be made for the passage of drainage-tubes. Disinfected rubber tubes, with fenestra should be inserted at such points and in such numbers that retention of discharges becomes an impossibility. They should be fastened by an antiseptic silk suture and cut even with the surface of the skin.

It will be necessary to pass by other details in the management of the wound, to speak of the dressing that should be applied. The object in view is two-fold:

1. To prevent the entrance of germs and provide for the discharge.
2. To secure immobilization of the fragments.

TO PREVENT ENTRANCE OF GERMS.

Irrigation of the wound region, having been constant until the time for dressing has arrived, is discontinued. The whole surface of the wound is then sprinkled lightly with iodoform, and covered with disinfected, protective or rubber tissue, which has fenestræ opposite the drainage tubes. The protective should be thickly powdered with iodoform. Then apply loose antiseptic gauze to the wound, and pad the whole region as thickly as the probable amount of discharge may demand. The fragments are now firmly held in perfect apposition and an antiseptic bandage is applied to the limb to bind on the gauze with equal pressure and moderately tightly. If the injury be at the lower part of the leg, then this dressing would extend from the toes to just below the knee. If the gauze is applied properly, it alone will furnish considerable support, and it will absorb discharges very nicely. Now take several long strips of tin, which have been roughened by punch-holes, and mould them to the leg and foot. They should be long enough to extend from the toes to the knee-joint. These pieces of tin must be perfectly aseptic also. Having moulded them properly, bind them in position with an antiseptic bandage. Thus will be formed a pretty firm support.* Thick as it is already, the antiseptic dressing should be re-inforced by a liberal quantity of antiseptic cotton, which should be properly secured by antiseptic bandages.

TO SECURE IMMOBILIZATION OF THE FRAGMENTS.

The contiguous joints, flexed to the proper degree and padded with cotton, must be immobilized by the splints. Suppose for convenience of description that the tibia and fibula are fractured. The best external splints for such a case are an anterior and a posterior splint, which extend from the toes to the upper third of the thigh, and are made with cheese-cloth and plaster-of Paris. For making such splints, the following suggestions will prove to be reliable.

For the anterior splint, cut three layers of cheese-cloth long enough to pass from the toes to the middle of the thigh, and wide enough to cover one-half the circumference of the foot, leg, and thigh. Three more layers of cheese-cloth are cut of the same length as the first, but about one inch and a half narrower. Finally, three layers of cheese-cloth two inches wide, of the same length as the former, are prepared. For the posterior splint, cut five or six layers of cheese-cloth wide enough to cover one-half the circumference of the foot, leg, and thigh, and long enough to extend from the toes to the middle of the thigh. Of course, in measuring these strips allowance must be made for the increase in circumference of the limb made by the dressing and padding. Having prepared the cheese-cloth, a plaster of Paris cream should be made. To prepare this, take the best plaster that can be obtained, and be sure that it is free from dirt and moisture. Into a basinful of quite warm water, in which a handful of salt has been dissolved, stir the plaster slowly until a moderately thick cream is made. The anterior splint should be passed through the cream first. Saturate the widest pieces of cheese-cloth first, and lay them upon the limb and smooth them down nicely, and then saturate the second three layers of the anterior splint with the plaster cream, and apply them to the limb. Finally, saturate the narrowest strips with the cream, and lay them upon the median line of the former layers, and smooth all down nicely, and add more plaster with the hands. If you intend to suspend the limb, iron rings should be passed

*Dr. W. F. Fluhrer was, I believe, the first surgeon to suggest this use of tin strips.

upon the narrowest strips of cheese-cloth before they are applied to the other layers. The posterior splint is now put through the plaster cream and saturated with it; then it is applied to the posterior surface of the foot, leg, and thigh. The manœuvres must be performed with celerity, or the plaster will set before the next step in process is taken. Such an accident endangers the value of the splint, which is apt to crack at important points, and be weakened thereby. Having placed the anterior and posterior strips upon the limb, they should be held in proper coaptation and bound upon the limb by plain crinoline bandages, which have been moistened. Of course, any description of bandage may be used instead of crinoline, but the latter when dry is quite firm, on account of the starch contained in it, and is, therefore, better than the ordinary muslin bandages. The limb may be held by assistants for a few minutes until the plaster is dry, or it may be supported on pillows; after the plaster has set, the limb may be supported by slings passed through the iron rings."—[See *Medical News*, December 1, 1883, p. 598.] It is important that the limb should be raised to a higher level than that of the body, and the splint must be allowed to harden with the knee-joint slightly flexed.

Some surgeons favor the roller bandage splint, which encircles the dressing. Sometimes fenestræ are cut opposite the wound. There are several good objections to that sort of splint. In the first place, I saw one patient bleed to death because the hemorrhage was concealed by the plaster, and was not discovered until the patient was beyond all hope. When fenestræ are cut of sufficient size to enable you to apply a reliable antiseptic dressing, the splint is very materially weakened, and, furthermore, the limb is apt to swell when the plaster is cut away, on account of the inequality of pressure, and cellulitis is not an uncommon accident. Moreover, the splint soon becomes loose and therefore useless. Bracket-splints are not worth the trouble of manufacturing. In cases treated with them the fracture is almost certain to heal in a bad position, on account of the backward bowing of the limb. The splint that I have described and recommended may be used again and again. It always fits the limb; it is light, porous, and neat.

The subsequent management of the case should be intelligently studied. The antiseptic dressing may, in many instances, remain in position without change for two or four weeks. If the wound have been rendered aseptic, if drainage have been thoroughly provided for, if the dressings have been properly applied, there is no danger braved by permitting the limb to remain in the first dressing a very long time. During the first month at least, in a bad case of this sort, the patient's temperature should be accurately recorded four times, at regular intervals, every twenty-four hours. The patient's pulse should be studied attentively also. His diet for several days should consist of fluids, especially milk. And the action of his bowels and kidneys should be properly attended to. At the end of two weeks the dressing may be changed, but not earlier, unless there be some positive indication for it. A positive indication for redressing the case would be a high temperature, 102° Fah., which could not be reduced within twenty-four hours by a full dose of cathartic medicine. It is not uncommon for patients to have a temperature of 101° or 102° for two or three days after the first dressing. But the patient ought not to feel that temperature very much; and the thermometer should not register as high as 102° Fah. constantly for twenty-four hours. As early as the third day, the temperature should not be above 100° and should fall gradually below that point and continue to remain below it. Very frequently a little morphine will reduce the temperature, and very frequently light doses of quinine, gr. iij. to gr. v. t. i. d., will effect the same result. Small doses of tincture of aconite every half hour will often be efficient. If by these means the fever be reduced and does not recur again when the medicine is taken away, the wound need not be examined.

This method of dressing cases is new, I think, to this part of the country. You may find that you can hardly be satisfied to wait, so persistent will be the desire to see the wound. But I am sure that nobody will regret having exercised judicious patience.

The criticism that will most readily occur to one's mind at this point will probably be that the dressing which has been described is not only one that may be applied only by exercise of considerable care and attention to minutiæ, but that it is expensive; and both statements would be true. Nevertheless, the dressing is the most practicable, the safest, and the most satisfactory one, of a large number of different dressings that I have intimate practical acquaintance with. We were perfectly satisfied that it was by far the best method we had tried. A sufficient reply to the first criticism would be, obviously, that it is not possible in the practice of our art—confessedly the most difficult of all arts—to attain excellence, amid circum-

stances that threaten danger, by means that favor ignorance or sloth. Clinical experience, confirming theoretical prediction, has proven beyond all reasonable doubt, that the aseptic-antiseptic treatment of wounds of all varieties is the most scientific, and, therefore, the best. As regards the expense of the dressing, it is apparently large, not really so, for it is changed only at long intervals.

Stimulants are nearly always necessary at first, and tonics are indicated later on. But the constitutional treatment, although very important, need not be so vigorous as in those cases that are subjected to other kinds of local treatment.

The same thorough antiseptic precautions already described must be observed whenever the case is re-dressed, including constant irrigation with corrosive sublimate solution. The same care in every respect must be taken. It may not be agreeable always to be so watchful, but in the end it pays.

Many compound fractures will heal very slowly, delayed union must be anticipated very often, and non-union, especially of fractures of the humerus, need not surprise any one. Necrosis of the ends of the fragments, causing exfoliation of bone, will be expected in the majority of bad cases. When contiguous joints are involved by the wound, anchylosis, generally of the fibrous variety, will ensue, and must be treated early by as vigorous passive motion as the condition of the parts will permit. In old people, anchylosis is very readily developed in healthy joints, and should receive special attention. Should it not be practicable to move the joints sufficiently, on account of the complaints of the patient, the surgeon must administer an anæsthetic and proceed with the treatment. For in such patients, when anchylosis becomes well-marked, it is very seldom managed successfully.

In spite of all your care and skillful attention a number of this class of compound fractures will not do well. And having attempted faithfully the conservative treatment you must amputate the limb. The advent of blood-poisoning must be noted the instant it becomes manifest, and, should it become unmanageable, it is imperative to amputate early, before the patient is much weakened by the disease.

With this imperfect sketch, I must leave the second division of our subject, and hasten to a conclusion. I do not wish to encroach upon your time and patience much further. To enter upon an exhaustive discussion now, would be indeed most serious business. I must, therefore, content myself and perchance delight you with a very brief reference to the third class of compound fractures. Cases which I would group in this category are, as a rule, the least dangerous to life and limb of all compound fractures of long bones. The wounds are small, and the fracture usually a result of indirect violence. The soft parts are only moderately lacerated, the larger arteries, veins, and nerves uninjured. In a certain number of cases, some difficulty will be experienced in reducing the deformity. A sharp fragment may project through the skin and cause trouble. But enlargement of the wound, or resection of the bone, will remove every obstacle in many cases. Antiseptic precautions should always be observed in accordance with the description given at another part of this paper. Even though the wound be small, it communicates with the bone, and is large enough to admit myriads of bacteria. We should not relax our vigilant attention because the case is not a desperate one. Even the most trivial compound fracture, we must always remember, is a dangerous injury.

All wounds compounding fractures when due to direct violence, should be enlarged, and drained by a tube or by strands of antiseptic catgut twisted together. Small wounds, due to indirect violence, should be treated in the same way. Then, no anxiety need be felt lest there be retention of blood or pus. When the femur is fractured and the external wound is small, always enlarge the wound in the integument and fascia lata liberally, and drain the deeper parts with a rubber tube. In corresponding injuries of the arm, a similar plan should be adopted. Sometimes in cases of this class it is best to wire the fragments together. The indications for that operation have been given already. You may hesitate to perform such an operation in cases in which it is positively indicated. If you do so, beware!—for, sooner or later, you will have trouble on that account. Wiring bones together will not positively ensure union of the fracture, but it will secure many patients against non-union. In compound fractures of the humerus, if the splints will not hold the fragments properly, there is no excuse, now-a-days, for refusing to suture them together. The wound should be dressed antiseptically in the manner already described. The gauze and plaster splint may be used. I prefer to use plaster of Paris splints, for they may be so perfectly fitted to the conditions present. The limb should not be put up in the roller-bandage splint until the wound has healed, or the danger of secondary hemorrhage is past. When the wound has become a superficial ulcer, or when it has dwindled down to a sinus, during

the stages of necrosis, it is often advantageous to use the roller-bandage plaster of Paris splint. But, for reasons already given, I prefer not to cut fenestræ in the splints. When it is necessary to use a close-fitting apparatus, and also to dress the wound every three or four days, a light plaster splint, reinforced by thin pieces of tough wood, meets the indications excellently. The general management of the patient during the early weeks is the same for this as for the former set of cases. But these cases give rise to less anxiety, for they do well when properly managed.

Time will not permit me to attempt a more thorough discussion of the subject now. For taking leave of it at this point, however, I need make no apology. But, I trust that I have given some hints that will assist you in an hour of anxiety and doubt, and be then an abundant compensation for the patient attention awarded me to-day.

THE IMPEACHMENT OF THE BODY.

BY GEORGE L. BEARDSLEY, A. M., M. D.,
Of Birmingham, Conn.

Cervantes noted that "every one is as God made him, and oftentimes a good deal worse." To this couplet might be joined another, that our physical structure was of more moment to the Creator than it has ever been to ourselves, and that we have made our souls the worse for its crucifixion. There are institutions ably endowed and widely revered, that have to do with the manufacture of creeds, the dissemination of tracts and the exhortation to holy conduct; but very few of our philanthropists are seemingly aware of the possible depreciation or wreck of any faculty save the moral. An odd enterprise would that be of establishing here and there stations with employees to talk on pepsin, to labor with stomachs abandoned to depraved desires, or to apply the balm that oozes from hot venison or a juicy rib-roast to a penitent vegetarian. No herald of the good news how to be saved the gnawing weariness of indigestion has yet sailed from any port, and the fear is firm that before the griefs of a wayward stomach become a fit tea-table topic, or the wails of a valetudinarian are examined with a twentieth of the earnestness that waltzing or lawn-tennis is studied, Hygeia and her serpent will have donned sack-cloth, and the race irrevocably given over to the laying on of oily hands, the exorcisms of a seventh son, or a fellowship with spooks.

It is a query to not a few why they have a body, and the longer they look thereon the greater they picture the martyrdom of the soul. Could they have officiated at their own conception, they would mayhap have disowned the gizzard. This contempt for the body or indifference to its fruition or content, is a platitude that seems to be fathered by the same asceticism that generally makes "the good die first." Maurice tried to die by inches to intensify his sanctity, and no man before the time of Raphael was called pious who broke his fast. The "fathers" had grave doubts whether one could pat his belly and have any hope of being admitted into the galaxy of seraphs. To rank among the children of light required a reduction in weight, protracted exposure to hardships, an unsavory diet. Fuller, in his "Holy and Profane State," speaks of one of "a lean body and visage, as if his eager soul, biting for anger at the clog of his body, desired to fret a passage through it." One is inclined as he delves into the memoirs of the various paragons of the church to murmur that Juvenal's maxim was not read on the Mount.

It is not on record that any of these early saints were successful in discharging at will their mortal encumbrances. Not a few discovered that the paroxysms of a pinched stomach did not stimulate to holy living. It began to be less a heresy to occasionally measure inspiration by nice digestion—faith was found to ripen into "passionate intuitions" after a holiday of humor, or a ragout of rabbit. Luther thought bowling not incompatible with his sallies on error, and methinks the ale he drank fired his zeal for reforming the abuses in the church. Who that reads of Calvin can hesitate to trace the acrimony of his teaching to his sour stomach, or is not sure, after listening to Beecher in his talks about the life beyond, that this divine must have had toothsome steak and waffles for Sunday breakfast, and gained in grace among the Berkshire hills. The sallow dominie, the pallid statesman, and the abstemious nun, are ill-selected to give a fillip to purity, loyalty, or charity. Before the ruddy Hosmer, the stalwart Parker, and the burly Choate, the disciples of Pythagoras stand rebuked. Not by the cadaverous, grunty, and hungry Plotinus can a philosophy be evolved that is worth translating. The genius that is the guest of a body built up on oatmeal and turnip will wilt in the heat of dispute on deductions, or flag in the search for new creations. Irving was a happy writer because the administration of his internal republic was successful. Burns sang his most winning lays before the aromatic haggis and amid the hilarious cotters; and who dares believe that Humboldt could have grown so massive in

his generalizations and conceptions if fed on hard tack and sausage?

The list is not complete; the evidence is not all winnowed, but 'tis safe to strike an average and aver that in *belles-lettres*, commercial avocations, or the several professions, those who do the most good or exemplify the ideal nobleness of culture are not those who cripple the body, or are chary with the larder, or believe in a protracted Lent. If the various gynasiums for the Nous could be furnished with a painting of Jerome by Carotto, or if on our parlor-tables there could be scattered vignettes of Lord Bacon, bareheaded, in his saddle, defying the storm, a worthy service would such sketches render. They would hint to us to intersperse the daily plodding for the dollar and the anxious brooding on the morrow with yachting, cribbage, minstrelsy, and, mark you! with creature comforts, the messes that are highly nutritive and equally poculent, a roast of antelope, perhaps, or a delicious bouillon, followed by St. Paul's allowance of sherry (prescribed by a physician). It may be that there is no soul that is not worth a bid, but if the essence tallies at all with the impressions of its environment, paradise ought not to be gained by some spirits until they have sojourned somewhere and done penance for a miserly expenditure on the body. This by way of plaisanterie, but, with seriousness, it is a prejudice with us that there is as much of honor to a finely-developed body as to a graceful use of language, a spirited imagination, or well-bred manner. If we are to look for fresh or frequent creations in the region of the speculative or the contemplative, we must pay heed to digestion, add greater richness to fibrin, register the pulse less, be liberal in living as in giving or thinking. The athlete honors the Creator, and a well-fed body is an admirable propagandist of the greatest of the three virtues, charity. Would there were more *bon vivants* among us—not cormorants, not gourmands, not prize devourers of quail, but those who believe in a diet that tickles the palate and does not tax the gastric tubules too severely, solid and savory dishes, with a dessert of mirth and music—those who are not insane in eating, but sensible as to what they ought to eat; those who are not epicures because full to contentment, but connoisseurs of digestion.

It is American to complete a repast as rapidly as possible—a galloping consumption at dinner-time is among the national disorders. The "nooning" is a serious interruption to money-making, and haste to consummate this recreation distinguishes the toilers after lucre. Scarcely one in ten who patronizes a restaurant thinks of the pleasures of the service. They truly eat just to exist; and could they with a share of glory forego the needs of daily aliment, they would be abstemious. From this long spun-out procession of fast eaters is recruited the army of dyspeptics, snarlers, and pessimists, that haunt the fireside or roost on the accountant's desk.

It is surely not the tax on muscles nor the sapping of the nerve by thinking that makes us permanently gray or unduly fretful. The blanched cheek and withered palm and flabby leg are not witnesses of an overworked physique. The hod-carrier and the master of the spade sleep sweetly and find a green old age. No painful study nor self-communings about coming troubles interrupt the luxury of their living. Nothing is suffered to defer the season set for a meal. The Englishman gets his avoirdupois because of his bread and cheese, and jolly soul, the risus ambilis, the merry ditty or racy yarn, and the mug of beer restore the equilibrium, that intent devotion to business may have upset, between his liver and his wits. No feuds are fed, no hasty mastication is observed, no solicitude about some precarious lead mine is let loose at an inn. Johnny Bull may to us typify the braggart, or shadow the consciousness of individual worth, but albeit he puts to shame the ideas that obtain with us how to extract the sweets there are in living. The gout may embarrass him, but it seldom worries his neighbors as does the profile of a crusty vegetarian. Who ever heard of a dyspeptic Teuton? A honestly-bred Dutchman can never trace the outline of his spleen, and somehow has no use for a gall-bladder. These chubby fellows are the best customers at the stores of nature. At the table they tarry long. The dishes may to us be palling or of poor assortment, but they excite precious little commotion after a long acquaintance. Whatever a German eats, contributes to his good and growth, because of its serene digestion. To hurry him at a luncheon would be to engage his contempt. Their festivities are as protracted as they are frequent, and never abridged for business. The nappy lager stills anxieties about Western Union margins, and the hot sauer-kraut revives the spirits of a German broker disheartened at the C. C. C. & I. quotations. Seldom does a Dutchman feel a nerve snap; he curries no favor with blue pill or pepsin, and turns the last quarter of the race as sturdy as he entered.

Not until sentiment and æsthetics are so modified as to anticipate the cultivation of the physical graces, merry-making, and the perfection of

the cuisine in every family, will the logic of healthy living be divined. The stomach must be rated an honorable institution, and when "its solid stroke tells the being what's o' clock," its faithfulness must be handsomely rewarded. The table d'hote must be hailed equally as a rise in Erie stock. Business and other varieties of labor must alternate with picnics, and junkets, with symposiacs and minstrelsy—detectives must be hired to ferret out frauds on the stomach, and furnished with search-warrants to explore the commissariat of subsistence in every family for trichinæ, glucose, and sour beer—in every quarter the alarm must be sounded against saleratus bread and pugnacious doughnuts, and the doctrine of total abstinence from unctious sausage and cohesive pie-crust vehemently enunciated. Let a regimen be general that ministers to the cheery symmetry of mind and muscle, let the culinary art be amplified and the larder stocked through the aid of a nicer appreciation of the fitness of its contents, let jolly digestion obtain as a correlate to the happy expansion of genius, and the parlor will fast cease to be an infirmary, and a ruddier set of saints will appear, whose wit, vitality, and usefulness, will not swoon in the afternoon of the "chase for fame."

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Pneumonia.

The next patient is a young man nineteen years of age, a German, single, and a grocer by occupation. He was admitted last evening. His family history is negative as regards pulmonary and rheumatic diseases. Patient had an attack of acute articular rheumatism eight years ago, but has had no subsequent attacks. Three months ago he exposed himself to venereal infection, and he contracted a chancre on his penis, and this was followed by the formation of a bubo in the left groin which went on to suppuration, and this is still discharging. He also has phimosis. He has been in the habit of drinking four or five glasses of beer a day, but does not use strong liquors. Has never had malarial fever. Four days ago he was exposed to the cold, and shortly after he had a severe chill, and this was attended with headache, and followed by fever and a perspiration. There was no vomiting. The next day he began to cough, and had a sharp pain in the right side, and he discharged a clear frothy mucous expectoration, and complained of shortness of breath.

Gentlemen, here is a young and vigorous man struck down in full health with an acute inflammatory disease, the nature of which you might easily recognize from the appearance of his face and the character of his breathing. As a picture of acute pneumonia, you could scarcely imagine anything more vivid.

There is nothing in the personal history which has any special bearing upon his present disease, except that eight years ago he had an attack of articular rheumatism. There is a prevalent idea that croupous pneumonia is more apt to occur after, or in connection with, an acute articular rheumatic attack. This idea has arisen from the fact of the frequent association of croupous pneumonia and rheumatism in the same patient; for there often seems to be a tendency to an alternation of these two diseases. This man was taken ill suddenly on last Sunday with a chill, fever, and headache, and pain in the right chest. And he was brought in last night with a temperature of 105.2°, which rose at one o'clock this morning to 106.3°, and it continued throughout the night at 106.3°; and at 6 a. m. it was at 105.6°, and at 3 this p. m., 106.7° This is a condition of hyperpyrexia, or of extreme high temperature. Anything above 106° is certainly a hyperpyrexia. And with this high temperature is associated a respiration of 60 and a pulse of 128. And these are conditions which are beyond the limits of safety laid down by Wunderlich as the safety points in pneumonia. This is the fourth day of the disease, and he is now entering upon the fifth day. Since he was brought in he has been taking quinine hypodermically as an antipyretic. Fifteen grains were administered at nine o'clock this morning, but it does not appear to have had any pronounced effect. Now, there is one thing about this high temperature to which I wish to call your special attention. This is a very high degree of temperature, and it is one in connection with which you commonly see symptoms which are not present in this man. It is usually accompanied by more or less cerebro-spinal irritation, which is evidenced by convulsive movements of the clonic description, and by subsultus, and there is very apt to be a low muttering delirium. But this man's mind seems to be perfectly clear, and he has no delirium either at night or throughout the day, and he shows no evidence of spinal irritation, and there is no subsultus. And the absence of these evidences of cerebro-spinal irritation, I think, makes this very high temperature in his case an object of less concern than it would be otherwise. Still it is a symptom which should excite the gravest apprehensions under any circumstances. Again, you notice that his respirations are very rapid, being sixty to the minute. Now we shall find when we come to examine him that the disease here is in the upper part of the right lung. And a pneumonia in this location, even though not as extensive as a pneumonia at the base of the lung, gives rise to a great deal more disturbance of the respiratory function, and it is a more serious locality for a pneumonic lesion than at the base. This man is perspiring freely, as you see, and his tongue and lips are moist, and this, with the absence of extreme prostration and of any cerebro-spinal symptoms, constitute a very striking feature in this case, and is a departure from the ordinary. The affinity of croupous pneumonia to acute inflammatory rheumatism is shown in the tendency of both to a hyper-

pyrexia; and excessive acid sweating is, as you know, a common feature of acute inflammatory rheumatism. Excessive sweating is certainly a feature here, and it has an acid reaction to litmus paper, which it turns red.

Upon percussion here, I find marked dullness upon the right side just under the clavicle, and I suppose the signs of consolidation are more marked behind. Upon auscultation, I get distinct bronchial respiration and bronchial cough above, and abundant dry friction rales in the lower portion of the right chest in front. There is always with pneumonia a certain amount of pleuritis, and there is never a pleuritis without some adjacent pulmonary consolidation.

The question of treatment here is one of very great importance. This very high temperature presents the indication of greatest moment. A hyperpyrexia you must try to control with every agent at your command. So very energetic means must be adopted in this condition. It is for the relief of this condition that cold effusions and cold bathing have become generally adopted. And I suppose that there is no measure which has so immediate and so marked an antipyretic effect as a cold bath which is gradually cooled down from a temperature of 80 or 90 degrees to 50 or 60 degrees, with the patient in it. In this way you can reduce the bodily temperature 5 or 7 degrees in a very short space of time. There is no better illustration of the exhausting effects of a high temperature than is witnessed in those cases where this high temperature is suddenly checked by the cold bath. I have seen patients suffering from an acute rheumatic fever, tremulous with spasm of all the muscles, and with low muttering delirium and a dry tongue, put in a bath of 80°, which was then cooled down to 50°, and the temperature having been reduced 5° or 6° in as many minutes, they were then put back into bed with the muscles perfectly steady and the mind illuminated so that they would answer questions. And I have then seen the cerebro-spinal irritation return with the rising temperature, and again made to disappear by the use of the cold bath. And in several instances patients have been snatched from the jaws of death by the energetic application of this cold water treatment of high temperature. There is no remedial agent that I know of which can be so much relied upon to reduce the temperature promptly and efficiently as the cold bath. But I confess that I cannot say that it is perfectly safe to put a patient with pneumonia into the bath. I never dared to do it, but I don't know but that we ought to have courage to try it. Yet those cases where it has been tried are not very conspicuous for their success. So I should not resort to it here. There are other antipyretics which may be employed. Quinine has signal and specific powers in the high temperature of malaria, and I think it also has a good deal of power in the high temperature of croupous pneumonia. In many instances I think I have seen it produce very decided effects, but it does not seem to have accomplished much here. But quinine is not the only antipyretic we have. Salicylic acid is another, and it is especially valuable in rheumatic affections and in the hyperpyrexia of rheumatic fever. I am inclined, in view of the association in this case of previous attacks of rheumatism and this pneumonia to try it here, and possibly it may have more effect than the quinine. We will therefore put him on doses of twenty grains every two hours.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM GOODELL, M. D.,
Professor of Gynæcology in the University of Pennsylvania.
Reported by WILLIAM H. FOX, M. D.

Carcinoma of the Cervix Uteri.

GENTLEMEN: While waiting for our patients to be made ready, let me say a few words to you in regard to cancer of the neck of the womb. We have two cases for treatment to-day, and let us consider first as to the best operation to be performed.

Some gynæcologists advise total extirpation of the uterus, and this is a good operation, provided you see the patient before the uterus is fixed; but unfortunately the onset of this disease is not attended by any pelvic pains and aches greater than those evoked by ordinary uterine troubles, and they are disregarded. You therefore generally find the uterus fixed either by cancerous infiltration, or by inflammatory exudation. This puts extirpation out of the question. The operation by extirpation is far from being free from danger; some patients die on the table, and others die in a few hours from shock, hemorrhage or peritonitis. The mortality is large, and even if the woman should recover, the disease is very likely to return. Now is the physician justified, knowing the peril of the operation, and knowing the likelihood of relapse, in performing the operation? I for one am still in doubt on this point. I performed this operation last fall; the womb was freely movable and was easily extirpated per vaginam.

In the operation of extirpation by the suprapubic method, the recti muscles are found tense and the womb low down; it is a difficult operation at best, almost impossible in a fat woman, and beside, one runs the risk of including the ureter in the ligatures, a misadventure always ending fatally. The operation per vaginam is easier in performance if the parts are sufficiently lax. The vagina is incised around the cervix, and stripped off. The anterior and posterior cul-de-sacs are opened. To facilitate this, a strong ligature is passed through the cervix, by which the womb is dragged down and pulled backwards and forwards as required. An obstetric crochet is passed into Douglass' pouch and hooked over the fundus, which is now pulled down through the wound into the vagina. A ligature is next passed through the fundus of the retroverted womb, and traction made on it. This brings the broad ligaments within operative reach. One of them is ligated en masse. It is then transfixed by a double ligature, tied, and cut off close to the womb. The other broad ligament is tied and severed in the same way, leaving the ovaries and fimbriated extremities of the oviducts behind. A very few stitches close the vaginal roof, excepting the point where the ligatures come out, and the vagina is packed with absorbent cotton, thickly covered with iodoform.

My patient died from peritonitis on the third day. I do not know why, for every antiseptic precaution possible was taken. So, as I said before, I am still on the fence. A couple of years ago I appointed a day for the same operation on another patient, but on the day before the woman went off into uræmic convulsions, and albumen in large quantities was found in the urine. I, of course, did not operate, although the poor woman, who clung to life most desperately, begged and implored me, by tears, by prayers, and by the most piteous entreaties, to remove her womb. It was a very sad case, and I shall never forget it.

The operation I prefer is to remove as much of the cervix uteri as possible, by incising the vagina at its junction, and stripping it up as far as possible without wounding the peritoneum, or the blood-vessels which lie in the broad ligament. This denuded cervix is then cut off with the curved knife of Paquelin's thermo-cautery, and the stump is then well charred by the platinum button. This, in the majority of cases, makes a very effectual oblation of the diseased parts, for fully one-half to two-thirds of the womb is removed. The success attending this operation is great; and sometimes the surgeon will be rewarded, as I have been, by a cure. One cannot always perform this operation, for the extent of the disease, or the peri-uterine exudation may make it impossible; but I think it is the best, and it is certainly not very risky.

Three times I got into Douglas's *cul-de-sac*, but no bad results followed. In my last case I did not find it out till I saw the intestines gleaming through the wound. I sutured the parts with silver wire, and the lady made a good recovery without any bad symptoms due to the accident.

The patient whom I now bring before you is the one I examined two weeks ago in this clinic, and you all will remember the free bleeding which took place from the gentle touch of my finger. Generally the hemorrhage is very free, sometimes dangerously so during the operation; but by injections of undiluted vinegar, and by working rapidly, one can ordinarily avoid an excessive loss. Yet a friend of mine, a very able surgeon, lost a case on the table from hemorrhage.

In one of my cases the hemorrhage came from an artery as large as the radial, and matters looked squally; but I succeeded in seizing the vessel with a pressure-forceps. At first I intended to leave it on for forty-eight hours, but finding that the vessel could be pulled out somewhat, I ligated it by twisting a silver wire around it. Wire was used instead of silk, because the latter could not be tied in so confined and deep a place as the bottom of the wound. Bleeding usually ceases when the sound tissues are reached. This patient is a multipara, and I wish to impress on you one point as important. A cancer of the cervix, in my experience, always occurs in women who have borne children, and not in virgins or in sterile women. This is owing to the fact that the raw and irritable surface of a torn cervix, with ectropion, presents all the circumstances favorable to the development of cancer. So, if a woman who has borne children, comes to you with a history of uterine hemorrhage beginning after the menopause, you will suspect at once that she has had a lacerated cervix, which by constant irritation has degenerated into cancer. Malignant disease of the body of the womb does occur, but it is rare, and in my experience is generally a sarcoma, and is a disease more peculiar to old maids and to sterile women. I often ask the question in the final examinations: what should your off-hand diagnosis be, were a lady, past the climacteric and the mother of several children, to come to you with a history of uterine hemorrhage? The correct answer is, "*Cancer of the cervix uteri*," and am always vexed when I do not get it, because it is a practical question, and one which I harp on very frequently in these clinics. Another question which I ask is: supposing an old maid or a sterile wife, approaching the climacteric, comes to you with a history of menorrhagia, what should you suspect? The answer is: Some benign growth, such as fibroid tumor, polypus or fungous vegetations of the endometrium. It might turn out to be a cancer or a sarcoma of the body of the womb, but that would be exceptional. Benign growths are the rule in such cases.

In the case before us, the disease has advanced too high up, and the peri-uterine exudation or infiltration is too extensive, for me to amputate the cervix in the way which I have described, and I must remove it in another way. With the fingers of my left hand, so as to keep a clean right hand —the obstetric hand—I tear away as much of the fungous mass as possible, and, to prevent hemorrhage, as rapidly as possible.

(*To be continued.*)

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Dr. D. A. K. Steele, President.

Regular meeting August 4, 1884.

Dr. J. H. Etheridge read a paper on

The Etiology, Pathology, and Treatment of Cholera.

The following abstract of the treatment in the paper, contained along with the discussion, is herewith presented:

The treatment of cholera to-day is changed but very little from what it was sixty years ago. Innumerable attempts have been made to change and improve it, but all have been to little or no avail. A better idea can be obtained of the new efforts in trials at improving cholera remedies perhaps by giving the treatment of three score years ago, and afterwards giving briefly an enumeration of the various additions to treatment recommended from epidemic to epidemic than in any other way.

"Calomel certainly comes next in order, and when employed in proper doses with the assistance of opium, and more particularly in the early stage of the disease, seems to be equally effective among natives as venesection among Europeans, in arresting its progress.

The outline of treatment alluded to is to administer 20 grains of calomel, and to wash it down with 60 drops of laudanum and 20 drops of oil of peppermint in 2 ounces of water, and to support the warmth by external heat, the hot bath, and hot friction, and internally by cordials."

Thus wrote Dr. James Johnson in 1824, in his classical work on "Tropical Diseases."

The discussion this evening will indicate how much substantial progress has been made beyond that of sixty years ago. *Then* the idea seemed to be "to start the bile"—as the expression then was—and afterward to quiet with opium and support the powers of life. Are we much in advance of this treatment in 1884? *Nous verrons.*

The epidemics succeeding 1817 seemed to call out the following remedial agents. The writer finds mention made of none of them prior to the dates accompanying them. The mere enumeration of them will suffice to show how lamentably fatal cholera has been, and how helpless medical skill is in rescuing human life from this scourge. Many remedies that we now see heralded in print as new and wonderful in curing cholera are very old. Many remedial measures are mentioned in these lists which provoke a smile of pity or of incredulity.

The epidemic of 1826–27 called out the following named agents as useful in curing cholera: carbolic acid, hydrocyanic acid, nitro-muriatic acid, alum, antimony, arnica, bismuth, buchu, cauterization, chlorine, counter-irritation, cupping, enemata of cold water, gold chloride, oxygen, purgatives, sodium chloride.

The epidemic of 1832–34 brought out the following named remedies. The lengthy list of agents is perhaps explained by the fact that the epidemic was a terrible one in its severity and mortality: Sulphuric acid, albumen, alkalies, ammonia, bandaging, baths of hot air, baths of nitric acid, baths of sand, baths of vapor, belladonna, bile, bladder injections, blood transfusion, cinchona, coffee, columbo, copper sulphate, creasote, diuretics, electricity, evacuants, enemata of narcotics, enemata of salines, enemata of tobacco, guaco, hæmospasia, horse-radish, ice, inhalations, injections—venous—saline, ipecac, iron, juniper berry oil, lead, ligature, lime water, milk injection—venous, musk, nitrous oxide, oil cajuput, oil croton, percussion—tapping on the abdomen, salines, stimulants, strychnia, sudorifics, tourniquet, turpentine, water—cold.

In 1848 the following remedies were brought forward: Hydrochloric acid, anæsthetics, arnica, camphor, capsicum, carbon, carbon bisulphuret, chloride, chloroform, ergot, ether, gunpowder, hydrotherepie, matico, metals, naptha, napthaline, silver nitrate, silver oxide, sulphur, cold, zinc oxide, zinc valerinate.

The epidemic of 1854 brought out the following named remedies: Alcohol, calcium chloride bath, cider—hard, cinnamon oil, eupatorium, garlic, movement, oil castor, potassium permanganate, quassia, sugar, vaccination, water injection into the peritoneal cavity.

The following named remedies were suggested during and following the epidemic of 1865, '66: Carbolic acid, nitric acid, nitrous acid, air—insufflation of, amyl nitrite, calabar bean, chloral, chlorodyne, coca, dosimetric treatment, hypodermic injections, magnesia sulphate, potassa liquor, spinal ice-bags, water—hypodermically, wine—lavements of woorara.

The only untried remedies suggested in 1873 were sulphurous acid, antimony, chloralum.

In the discussion, which consumed nearly three hours, Dr. I. N. Danforth gave the pathology of cholera from studies and researches of the disease. Every organ of the body, said he, is more or less affected, but there are three lesions that are apparently uniformily present, namely, the blood, intestinal canal, and in the kidneys. This, I say, appears to be uniform. The blood in the early stage becomes thickened and may not flow; it is sometimes stationary, and is filled or invaded with microbes, or other living organisms; they are not related to the causation of cholera, and the same variety is not always found in the blood, in the intestinal canal, or in the discharges. Cholera is not produced by any specific germ. The blood loses its watery portion with great rapidity and to great extent. In 1873, during the localized endemic of cholera here, he investigated specimens of the discharges of the intestinal canal from both ante-mortem and post-mortem cases, and in each he found vast numbers of micrococci, and other low organisms, but he is sure they had nothing to do with the causation of cholera, but that there was formed a nidus for their development.

Ziegler, Lieber, and La Barra, or La Blat, according to Ziemssen, assert the same thing to be true, and that they are incidentally there, and "spring up" in the intestinal fluid; or, in other words, it is a field for them.

The speaker demonstrated his remarks by illustrations on slides from portions of the intestinal canal and fluids that he had mounted. The first drawing represented a piece of the intestine about the middle of the attack of the disease, and showed a grouping of cells and granular matter. Some authors state that the intestinal epithelium is not discharged until after death; but I am positive they are thrown off before death as well, that the canal is stripped of its epithelial coating while the patient is living, or that the villus is stripped off; or, if you choose to state it, the villi are stripped from their coating of cells.

A specimen of the ileum was shown, representing a portion of it from about ten inches above the valve, and the cellular coating of one of these villi specimens of Peyer's glands were shown, and illustrated their swollen or distended condition, with a group of cells and many nuclei.

The whole surface of the lining of the intestine becomes very red, or of a bright pink color, and ecchymotic patches form. The arteries are less distended, but there may be formed an enormous amount of stagnant blood in the intestinal canal.

The Lesion of the Kidneys.—At an early stage of the disease the organs undergo a rapid fatty change; they become enlarged; so too does their cortical portion. This acute fatty change rarely ever becomes chronic should the patient recover (he was sure it did not become so if the patient died). The liver, the spleen, the brain, and spinal cord, may sometimes become hyperæmic; doubtless they become so quite often. Now these changes do not throw a great deal of light upon the cause of cholera, if any at all. Indeed, we have not arrived at the cause. Those writers and authors who state that there is a specific cholera germ, but do not state what it is, are not positive. Koch believes he has discovered the germ, but his experiments to prove it thus far have been futile. Lesions occur in the small intestine, the rectum included, due to an invasion

of germs or a virus, of which we do not know as yet what it is, and its effects further determine to the emunctory organs and affect depuration. First, the intestinal discharges, and on that ground the blood loses its watery and saline element, and the kidneys fail in their function.

Dr. W. T. Belfield, regarding a special organism, he would first state his knowledge upon this subject was in one sense second-hand. He would endeavor to recapitulate briefly Dr. Koch's discoveries whilst he was in Egypt and India. There is constantly present in the wall of the intestine an organism that is easily recognized by reagents and stains, that are never present in the blood or any of the organs of patients who die from other diseases or causes. However, this does not prove that this organism is the cause of cholera, or that the cause of relation exists as it does in some other infectious diseases, notably one or two as will be mentioned later. The association may be explained in one or two or three different ways. Of course, it may perhaps be a cause. To decide this (a matter quite impracticable or unlikely) would be to inoculate a human being, to produce the disease by separating the organism from the juices and transmitting it to a healthy human, the same as a healthy animal can be inoculated with anthrax. Koch states that there is a specific germ that is constantly associated with cholera, and that no other germ is present; but when he applied the crucial test of separating that organism and endeavored to inoculate dogs, cats, and white rabbits, his experiments failed. But on the other hand this does not prove or disprove that there is a specific germ to cause cholera, for none of these animals will take cholera. They are immune from the disease, although there may be certain domestic animals that will contract the disease. The bacillus alluded to by Koch, as he asserted, is always present and distinguishable from other organisms, and they rapidly multiply. In relapsing fever are found other low organisms. The spirillum is always present in the acme of that disease. I think the germs that exist in choleraic discharges are in the relation of association only. Regarding their natural history, they flourish most in a slightly alkaline fluid, and acids destroy them, and are or should be a principal adjunct to the treatment of cholera.

Dr. John Bartlett, upon invitation, gave the results of some interesting experiments made in 1874, on a fungus, and his deductions therefrom, which are as follows: The fungus undergoes phases of development; first it is a cell (come vaselis), and is the active agent to alter and impair the blood and tissues. This, we suppose, is ultimate. In ague it is a cell in a developing fluid, but does not rest as a cell. It aggregates and deteriorates tissues. These cells form a certain crystalline something. This crystalline substance is not lifeless; it puts forth buds; these set forth a fluid; it is homogeneous; it apparently is nothing, yet it is a protoplasmic fluid, and there exists a cell form of material crystalline substance—a bud—a fluid which is protoplasmic and cells form again identical to those that were first formed. The cells, too, may be inert and not self-multiply, the protoplasmic fluid is not recognized in the blood, invisible atoms become visible atoms. Dr. Koch's experiments thus far have given unsatisfactory results. He may demonstrate the micrococcus, or bacillus, so that it can be seen with the naked eye. Protoplasmic fluid is not recognizable by the aid of the microscope until cells are developed.

Dr. C. G. Smith stated that there seemed to be many points to settle at this time relative to the contagiousness of cholera; all the old theories in this respect seem to be changed. Years ago he made up his mind that it is highly contagious; he had been surprised to see a woman with the experience of Florence Nightingale pronouncing against this theory. Some physicians state, it is scarcely necessary to take any special precaution to prevent contracting the disease. Some French physicians, it is reported, were so enthusiastic upon this, that they have tasted—drank—the discharges from patients dying of cholera, and did not take the disease. In 1854, he believed, it had been demonstrated that the discharges were contagious. Not when they are fresh, but when it ferments and has decomposed. The whole history of the disease proves its communicability. In India moisture and filth propagate the disease, and it becomes started on the grand march along the great lines of travel around the world. This it does not quite do, for he never heard or knew of an outbreak of it in Australia. This looks to him as though the scourge could be "stamped out" by vigorous executive quarantine measures, and we should quarantine ships before they reach this continent, where there are lurking suspicions of cholera aboard; for if the disease should come here and travel along our railroads to cities not along the sea-board, it is a much more difficult matter to "wipe it out." In the last epidemic in this city there seemed to be a focus of cholera at Butterfield and Thirtieth streets, and twenty cases of cholera "sprung up" at once. The inhabitants were removed, the houses were fumigated, and the other premises were cleaned and purified, and the disease was immediately "stamped out." It is a malignant poison, and finds its way into the intestine, and nature makes an heroic effort to rid the system of it, by profuse perspiration, pouring out of serum, all of which is analogous to an eruption. The result of the morbid symptoms is purging and vomiting, thickening of the blood, want of urinary secretion by failure of the kidneys to act, appearance of cramps, etc., etc., until a final stage of collapse and death is reached.

A letter was read from Dr. John H. Rauch, Secretary of the Illinois State Board of Health, as follows:

"SPRINGFIELD, ILL., July 29, 1884.

"*Dear Doctor:* I am in receipt of your letter of the 24th inst., asking if I have any sanitary suggestions to make for the benefit of the society and the protection of the health of the city, in view of the possible danger of an epidemic.

"As a matter of public policy, I think it better that such suggestion with reference to Chicago should originate with Dr. De Wolf, and in my judgment he is doing all that he can with the resources at his command. The Chicago Medical Society, however, may strengthen his hands morally, and possibly help to increase his material discussions, as are proposed. The condition of the river, and especially of the South Fork, is a

matter of the utmost importance to Chicago in the event of a cholera epidemic—and, indeed, at all times. Sixty thousand cubic feet per minute, transferred from the river to the canal, will keep the former clean and harmless; will prevent the possibility of pollution of the water-supply at the crib; will affect 66 per cent. of the South Fork, and will so dilute the sewage as to make the canal unobjectionable to the communities along its banks. To secure this transfer requires two things: 1. That the pumps at Bridgeport be operated to their full capacity. 2. That the waters of the Des Plaines river be prevented access to the South Fork through the Ogden ditch.

"If the society can achieve this, it will render a most important service to Chicago; will help De Wolf in his arduous work, and earn the gratitude of 150 miles of cities, towns, and hamlets along the canal and Illinois river.

"Very truly yours,

"JOHN H. RAUCH."

Dr. C. W. Earle stated that men of his age had not passed through epidemic cholera, as a physician, he could therefore say nothing regarding it from experience, and preferred to hear what our older brethren had to state in this respect. Regarding the differential diagnosis of infantile diseases he could, were it germane to the subject under discussion, add something. Or, were Asiatic cholera present, infantile diseases could be discussed simultaneously. He thought diseases of children, especially the summer bowel difficulties they have, should concern us more at this time than cholera. He would at an early date, if desired, say something as to how a remedy may be devised to diminish the great mortality among this class of our population.

Dr. N. S. Davis was invited by the president to give the history of differential diagnosis, and his treatment of cholera and cholera morbus. He stated that he felt embarrassed to discuss a subject of this kind before the society. As the time for doing so was limited, and he was afraid that he would consume more time than belonged to him, and to do so hastily would prove unsatisfactory to himself, as well as to others. He had studied cholera in epidemic form clinically, in a large degree, since 1849. In the city of New York, where he lived at that time, it prevailed pretty extensively. He remained there until the epidemic subsided, and administered to those afflicted with the disease for twenty-one days and nights consecutively. He has seen more or less of epidemic cholera when it has appeared here since that time. During the fall of that year he removed to Chicago, and we had it here also during the summer of 1850, '51, and '52. In the summer of 1853, Chicago was clear of cholera, and there was no semblance of the disease, but in 1854 it "broke out" again. The first case appeared in the western portion of the city on about the 20th or the 24th day of April. Cases "sprang up" disjointedly in different parts of the city every three, four, five, or six days during the months of May and June, and eight or ten deaths a day occurred during the last days of June (although the newspapers stated to the contrary). He then gave a number of interesting reminiscences, how the authorities quarantined down the Illinois river to prevent the disease entering Chicago from the interior of the State. In 1866, when it again appeared, he pushed his last resources to prevent its becoming epidemic, and quite exhausted his powers of vision to discover the power of its contagion. He kept the alvine discharges of patients who had the disease for one or two weeks to discover this, and had in his possession now drawings that he made at that time. So far as the disease is concerned there are a half dozen different varieties of germs; they are accompaniments of the disease. And every variety of disease having a degenerative accumulation of natural cells in the tissues, is invested or accompanied by some form of germs. Wherever there is a deteriorative change of living organic matter, or where dissolution is reached, no matter what the disease is, germs are present, not as causes but as accompaniments. They are uniform, and are accompaniments of the effects of the disease. Some writers may produce the disease by inoculation, but he had not known of this being done. In 1848 he recalled two instances of steamships crossing the ocean; they came in about the same length of time as vessels do now; perhaps, though, it required a day or two longer. But cholera does not come with the tide of travel, although it spread over Europe during that year. One of the vessels was destined for New Orleans, the other bound for New York. The latter was quarantined, as two or three emigrants on board were attacked with the disease. They were taken on shore to a boarding or lodging house on Washington street that contained 400 others. Yet cholera did not spread; it "died out" at quarantine. This occurred in either November or December of that year. The vessel bound for New Orleans arrived there, and cases of the disease appeared on board the ship *ere* she got within 500 miles of New Orleans. The vessel was not quarantined, and the result was cholera developed furiously in that city. In the spring of 1849 it "started up" again in New York, and spread over the country, although vigorous measures were pursued to "stamp it out." This cannot be done, however, and we must look to see it "die out." It will not prevail for more than one or two seasons in succession as a rule, although in this city, during the years 1849, '50, '51, and '52, proved an exception. Regarding the theory of germs and propagation of the disease, during the year 1854 no one disinfected the discharges. There were no cess-pools but what some of the dejecta were emptied in, and these, too, were not disinfected. Yet cholera did not appear in Chicago again until 1866. Of course, though we should exercise vigilant sanitary precautions, for the disease cannot flourish in an elevated position where there is an abundance of fresh air and pure water (the Kætskill mountains were mentioned as a point of illustration, where the disease cannot obtain a foothold), yet the disease was prevalent in Europe in 1865. We anticipated its coming to this country and visiting this city the year following, and many of the timid ones made their arrangements for getting out of the city early, and he advised any physician who was afraid of getting it, or if he believed it to be contagious, to remove when it makes its appearance. It began during the latter part of June, but not very vigorously. A few deaths occurred every day during

this month and throughout July. In August it rained nearly every day, and excessive moisture does not help to increase its virulency or prevalence. The result was cholera entirely disappeared. The agriculturists held their annual State fair during the first week in September. Farmers arrived and stopped at hotels where but a few weeks previously people died of cholera. The farmers returned home safely in good health, and did not take the disease. During the last two weeks of September the weather became very sultry and hot. The moisture and water of the August rains were dried, when cholera rapidly "sprang up" again, and one thousand deaths occurred in the following three weeks, which extended over into October. There was an unusual sharp prevalence of it. Then frost appeared, and a little later snow fell, and in another week no trace of the disease was left. Three things are essential to produce cholera where they coöperate together: 1. High temperature. 2. A location where the soil is in a damp condition favorable for decomposition of organic matter. 3. Where an organism is in that soil.

Prevention.

Briefly then, antiseptic measures, entire cleanliness, and in this we need not look much beyond our own location to prevent it, alluvial soil must be looked to, fumigation and hygienic rules must be regarded. Relative to the differentiation of epidemic cholera and cholera morbus, we will hastily give the more prominent symptoms of each. In the latter disease the urine is seldom or never suppressed, there are more griping pains in cholera morbus, then too there is no preceding stage of diarrhœa, while in epidemic cholera, there is almost always a premonitory stage of diarrhœa lasting from four or five hours to as many days. It is a painless diarrhœa. There is lassitude, and there is sometimes a "crawly feeling" that "steals" over the patient, or a sense of numbness comes on, and there supervenes a strange prickly feeling. There are also noises in the head, or a stunning feeling about the head and ears, until he will have an attack of purging, and pour out a vast quantity in the chamber; the blood recedes from the surface. The patient attempts to lie down, but he is suddenly disturbed from this position by an attack of vomiting. He vomits and purges an unusual quantity of serum, and this process he repeats every ten or twenty minutes. The chamber may be half filled at one attack of purging or from one discharge. It is rice-colored or turbid in color, little flocculi appear in it, also mucus and epithelium, which settles to the bottom. The patient rapidly withers, his lips become leadened, in three or four more evacuations, he is seized with cramps, they appear first in the calves, then in the muscles of the cornea, the voice becomes husky and hoarse, he can scarcely speak above a whisper, there is no bile in the discharges, there is lowering of the temperature, the breath is cool. Sometimes cholera morbus will put on this aspect, and, again, a few cases of true cholera will differ from the above hurried description. A patient may be so violently attacked that in a few minutes he becomes faint or goes at once into collapse, or in from three to six hours collapse will come on, with perhaps only one evacuation of the bowels. The speaker then cited a typical case of this form of cholera, namely, that of a Norwegian laboring man. It is as if the vital forces are paralyzed at once.

Indications for Treatment.

If it were true that these little microbes caused the disease, and acids would kill them, then the first thing to do is to get acid into your patient, and kill the germs. Give them some form of the mineral acids, as the dilute sulphuric, sulphurous, or the hydrobromic acid; but we must not depend wholly on these to arrest the progress of the disease, we must immediately put the patient at rest. The mucous membrane in its entirety is an absorbing surface; in its first and middle portions, its action is changed or converted into a most rapid exudation. The surface of the stomach is exosmose in its action; there is relaxation of the cutaneous surface that needs to be attended to; the blood undergoes a rapid change as a result of the disease; the saline elements and watery portion of the blood are washed away; the blood becomes thickened, so much so, oftentimes, that it will not circulate; molecular change and heat cease. The vaso-motor nerves may be the first to take on this primary change in the disease. We must adopt measures to stop the inverted action of the mucous membrane. How are we to do this best? The speaker had tried every rational method of treatment that he could devise in former years, although he never had tried horse-radish or vaccination or gunpowder, as had been mentioned in the paper. He had cupped the spine, applied sinapisms over the epigastrium and spine, applied dry warmth and frictions, had seen patients placed in the ice-pack, and rolled in blankets wrung out of ice-cold water, he had applied salt and ice about the spine, he had used emetics of salt and mustard, had bled them by opening a vein when the blood would run, and this he had seen afford temporary relief. In a few instances emetics of salt and mustard he has seen help a patient. *The most successful method*, however, is to diminish the *excitability of the mucous membrane, lessen the tendency to wasting of the saline elements, and promote the action of the kidneys.* And first of all, the cholera patient should be placed entirely at rest in the horizontal position; then apply dry warmth to his limbs; do not apply friction, and if cramps appear, gently seize the muscles with the hands and compress them. Apply a large sinapism of mustard to the epigastrium, and when it becomes too hot, change it to a point opposite (on his back), or between the shoulders.

During the years 1866 and 1873, he gave internally the following powder: Calomel, gr. j., morph. sulph., gr. $\frac{1}{6}$, sacchar. alba, gr. v. After each attack of vomiting, do not wait to give it at stated intervals, for to do so it might be given the very moment he vomits again. Mix the powder with a spoonful of ice-water, then give a small piece of ice to satisfy the patient. Serve the rectum in the same way with an anodyne and alterative remedy by giving a powder composed of plumbi acetas, gr. x, morphæ sulph., gr. ss, in two ounces of cold water. This is to be used as an enema, and should be retained by assisting the patient to do so. The latter part of this treatment he has pursued since

1849. In addition to the internal remedies, he gives

℞.	Carbolic acid,	gr. $\frac{1}{4}$ $\frac{1}{5}$.
	Tr. opii camph.,	℥ss–$\frac{1}{3}$.
	Tr. gelseminini,	gtt. v.,

in a little glycerine and water alternately with the powder. These are very beneficial remedies to overcome the vomiting and assist the urinary secretion. Give other remedies also to favor secretion of urine, such as the diluent drinks. We should build them up and prevent collapse. Should this ensue, we must replenish their forces by giving any of the broths, such as beef tea or chicken soup, or rice boiled with meat, well seasoned with common salt to make up for the waste of the saline portion of the blood that has been washed away. Give also strong coffee in teaspoonful amounts at first every few minutes, and gradually increase this amount to act on the vaso-motor system; repeat it as often as every fifteen minutes, increasing the quantity steadily as it could be retained. His skin should also receive especial attention in addition to the above remedies, that are to be applied externally. Give a hypodermic injection of atropine to act on the periphery, combined perhaps with minute doses of strychnia, which may be introduced anywhere over the surface. Do not use ergotin, for this is depressing. One writer recently claims to introduce an equal mixture of whisky and water in the areolar tissues of the thigh until reaction comes on, will arrest further progress of the disease. I would suggest instead of this, that it consist of a saline water injection instead, to be used in the same manner. Such though is the outline in substance of the treatment to replenish most cases, and if persistently and carefully carried out, will in twenty-four hours bring about a fair chance in most cases for the patient to be on a good footing.

The Society thanked the Doctor for his address, and it was resolved to continue the discussion of the treatment of cholera at the meeting two weeks hence.

LISTON H. MONTGOMERY, M. D.,
Secretary.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Arrest of Hemorrhage.

In the *Glasgow Med. Jour.*, August, 1884, Dr. J. Stuart Nairne publishes the following practical remarks:

"I have been present at operations where one might truly say that it was only by the grace of God the patient did not die on the table from hemorrhage, as there were neither right nor ready means at hand for controlling it; where there was nothing better for tying the stump of a pedicle than a piece of whip-cord tightened by the hands; and any one who has seen this method of securing a thick stump, will not be very ready to try it. By no amount of manual pulling could you safely compress a vascular stump, say from an inch upwards in diameter. The vessels in the centre would be sure to bleed sooner or later, and I have seen one fatal case from this cause. In this case the operator had neither clamp nor compressing forceps, nor wire ligature to be screwed up; nor even the loop of an ecraseur to control the hemorrhage. In one public institution I saw a death on the table. The uterus was amputated at the cervix, while the stump was grasped by the hand in order to tie a ligature to it. Before this could be done, the patient was dead. It is right to state that this death was attributed to shock, and not to the loss of blood. If this was a death from shock, it is the only sudden death I have ever seen from that cause. I do not believe that death can ever possibly occur from that cause—viz., shock—unless some of the vital nerve centres be directly implicated, *always taking for granted, however, that the patient is properly under the influence of an anæsthetic.* Under these circumstances, and also when no anæsthetic is used, death may occur from the most trivial shock. You will remember a recent case when a highly respected surgeon of this city, examining a patient with inguinal hernia, found it suddenly slip from his fingers, and on announcing this pleasant fact abruptly to the patient, she immediately died. This was a death from pure nervous shock, and could not possibly have occurred under an anæsthetic. I do not believe a death ever occurred under an anæsthetic, unless from the anæsthetic itself or from some kind of blunder in the operation. Some years ago I assisted an operator, a quiet, bold man, now laid in his grave, in the extirpation of some deep-seated glands of the neck on the left side. The pneumogastric of that side was cut; its inhibitory action ceased, and the pulse and respiration rushed at unaccountable speed, bringing death in less than ten minutes. *De mortuis nil nisi bonum.* It was a blunder, we all said so—four of us then, and the two eminent of us since then laid in their graves: and this statement, a truthful little cross elevated over the one's tomb in no spirit of animosity, but as a valuable warning to us who remain. This is the kind of sudden death, then, that occurs under operation—error of judgment in doing, a slip, incapacity to control hemorrhage or surmount difficulties, or extinction of life by the anæsthetic.

"In a case narrated in a recent number of the *British Medical Journal*, Knowsley Thornton, who assisted the operator, passed his hand into the pelvis and held the stump of the uterus, which had been removed, till Koeberle's serre-nœud was applied. The case recovered; but such a course is not to be imitated. An experienced operator may do almost anything; but no one has the right to place the life of a patient in jeopardy either through temerity or carelessness, far less from a desire to show off his dexterity.

Every drop of blood that you save is a gain to your patient.

"I am sure many of you must remember as well as I do when an operation in our Royal Infirmary resembled, to a large extent, an exhibition of so many artificial fountains; I and my fellow-students have frequently been bespattered with blood as we sat in the benches. I remember an operation for ovariotomy in the Chapel, the old operating theatre of the Glasgow Royal Infirmary. The general circumstances are as fresh and horrible in my mind as yesterday. The incision—the uselessly long incision—into the abdominal parietes was followed instantly by torrents of ovarian fluid and blood, the operator thrusting his hand into the interior of the cyst and breaking up smaller loculi, which discharged themselves in the same way. Everybody and everything around was soaked. *Nous avons change tout cela.*

Pressure Forceps.—There need be no such display. Deliberation, quietness, the application of pressure forceps immediately you cut, or, when possible, before you cut, and your operation will be conducted with the greatest cleanliness and the least risk to your patient.

"The ordinary artery forceps are absolutely worthless for the immediate suppresion of hemorrhage. You have frequently neither time nor room to throw a ligature over a bleeding vessel in the usual manner; and, as I have seen, at a later stage of the operation the ligature and end of the artery may be cut off by accident. You can never make such a mistake with pressure forceps; for if you have to cut a little beyond or above them, you are bound to know what you are doing; you see the forceps attached, but you may not in your hurry notice the loop of silk or catgut.

"In an operation shortly since, which I had the pleasure of doing for Mr. Gilmour, eleven pairs of these forceps were attached at the same time to various bleeding vessels and surfaces; and I may refer to that gentleman and to Dr. Pollok, who was also present, to say if there could have been more than two ounces of blood lost in an operation that lasted for an hour and ten minutes.

"The use of these forceps is not limited to abdominal surgery; they are far too seldom used in general surgical work. Your President kindly assisted me the other day at an operation in private for amputation above the knee-joint. With the limited use of an elastic tourniquet, and the rapid application of half a-dozen pairs of forceps to the bleeding vessels, I think Dr. Park will bear me out in saying that there could not have been lost more than half an ounce of blood. In a long operation, by the time you are ready to tie the vessels you will frequently find the bleeding has ceased, and you will require fewer ligatures than you could have anticipated. It is a little difficult to slip a ligature on a vessel over the points of these pressure forceps, and you may require occasionally to put on an ordinary pair of forceps for this purpose, but very rarely indeed.

"These scissor or pressure forceps are of various sizes and makes, concerning which more particulars a little farther on. Those used by Sir Spencer Wells are admirable instruments; Lawson Tait's form is sharper in the nose, and he claims for them that their point is not so readily entangled in a ligature; the bulbous extremity which I have put on them, however, prevents any possibility of this happening. Pressure forceps, then, are a perfect *sine qua non* in an abdominal operation. It is important that there should be as little blood lost as possible, and it is also important that as little blood as possible should escape into the abdominal cavity.

A Curious Case of Persistent Reflex Spasm of the Diaphragm.

Dr. A. L. Ranney reports this case in the *Medical News:*

A case which I desire to bring before the notice of the profession was lately sent to me by Dr. L. M. Bingham, of Burlington, Vt., for diagnosis and suggestions as to treatment. Her history was as follows:

Miss E. W. Unmarried. Aged forty-four years. Her father died of cancer, complicated with phthisis, at the age of seventy; her mother died of heart disease at the age of thirty-five. She has three sisters living, all of whom are "delicate and of a nervous temperament." Two sisters died of Bright's disease. One niece of the patient had chorea of a severe and persistent type.

As a child, the patient was afflicted with "extreme nervousness," but never had any marked symptoms of chorea. She menstruated at thirteen years, but was irregular until she reached the age of thirty years, since which time the menstrual function has been normal. Insomnia became developed as a marked symptom at the age of twenty years. It has persisted ever since; but with varying degrees of intensity. From youth she has been subject to more or less tremor of the hands, and has lately noticed that excitement markedly increased it. The tremor stops during sleep and does not caused her much inconvenience during the day. Neuralgic pains occasionally shoot into the hands and fingers, and are often experienced in the shoulders, back, and left side.

Four years before the date of my examination, she was attacked with *paroxysms of hiccough.* These have persisted throughout the past four years. The attacks come on in paroxysms which last from ten to sixty minutes. They are often so severe as to cause vertigo and symptoms of asphyxia. *They almost invariably follow movements of the upper extremities.* For that reason all manual efforts have been avoided for some years. The sweeping of a room will throw the patient into a severe paroxysm of hiccough. Sewing is rendered impossible for the same reason. Dressing the hair almost invariably induces an attack. Movements of the head, trunk, or legs seem to exert no influence upon the patient of a similar character.

Of late, neuralgic attacks have become more frequent and severe. The eyes have been affected with neuralgic pains of a severe typs, and also the shoulder of the left side.

On examination, no loss of muscular power was detected by me in either hand by means of the dynamometer. The condition of her body in respect to sensations of tou ch, pain, and temperature was tested and foundto be normal. No painful points (the puncta dolorosa of Valleix) were

detected over the seat of the neuralgic attacks. Pressure made over the spinous processes of the vertebræ produced no pain *except at one point.* This corresponded to the situation of the fourth, fifth, and sixth cervical segments of the spinal cord. Here the patient suffered marked pain on pressure and the skin was markedly hyperæsthesic. The patient stated, in reply to my interrogations, that this region had been the seat of a continuous "aching sensation" for the past four years. The superficial and deep spinal reflexes were normal. Coördination was performed perfectly in both the upper and lower extremities. The pupils were normal and responded perfectly to light and visual accommodation.

The condition was evidently one of abnormal excitability of the lower cervical segments of the cord, associated with general neurasthenia. The fifth cervical segment gives origin to filaments which enter into the formation of both the brachial plexuses and the phrenic nerves arise from the third and fourth segments as well. The case appears to justify the conclusion (based upon anatomical data), that the activity of the lower cervical segments (necessary to movements of the arms and hands) produced in adjacent segments of the cord an abnormal irritation of the cells associated with the physiological function of the phrenic nerves—hence the diaphragmatic spasm.

The patient was burnt with the benzine cautery apparatus over the cervical and dorsal segments of the cord, and ergot and the bromides were ordered to relieve the local congestion of the cord that probably exists. This treatment had previously been tried for a short time with marked benefit, but had been discontinued when the symptoms exhibited amelioration. The effect of the continued use of the cautery has yet to be determined.

Acute Inflammation of Diabetes and Nerve-Influence.

In the course of his address in medicine before the British Medical Association, Dr. William M. Ord said:

In true diabetes, the occurrence of sudden and very acute visceral inflammations is common. It is generally found that, while such complications last, the urinary sugar dwindles, or even disappears. An explanation of this occurrence has been found by some writers in the hypothesis of an increased combustion of sugar as a part of the pyrexial state. But, seeing that such inflammations involve the diversion of a large quantity of blood to the organ affected, I venture to suggest that in such diversion, rather than in a purely hypothetical combustion, may be found the true explanation. Physiological experiment has shown that, when sections of the sympathetic, leading to vaso-motor dilatation of the hepatic vessels alone, has been made, glycosuria has been produced; that, when the section has been made at a point producing, in addition to dilatation of the arteries of the liver, dilatation of the vessels of the intestines, glycosuria has not followed. The inference drawn is to the effect that so much arterial relaxation was produced in the supply of organs neighboring to the liver as to stand in the way of an effective increase in its arterial circulation. I had an opportunity quite recently of testing the probability of this hypothesis. The temperature of a diabetic patient rose suddenly to 104° Fahr. The most careful examination brought out no signs of visceral inflammation during two days; and in the same period the amount of sugar in the urine stood at the figure registered for several weeks before. On the third day, the temperature remaining at the same height, the signs of pneumonia became apparent, and at the same time the urinary sugar diminished very considerably. In my gouty cases, a similar train of phenomena has been several times noted—the sugar diminishing in a very marked degree at the time of the development of acute joint-inflammation, and returning immediately on its subsidence.

In trying to understand the sudden acquirement of a poisonous quality by the milk of an agitated woman, one had found a difficulty of this kind—could mere quantitative variations in the afflux of blood affect the quality of the secretion? Can it be possible that, in the production of the lacteal secretion, may be concerned not merely increased afflux of the materials of the secretion, but also varying afflux of ferments determining its quality; and capable, by reason of either great deficiency or great excess, of seriously perverting its quality? Here is an admitted neurotic dystrophy, the mechanism of which is well worth careful investigation; and from the consideration of glycosuria we may be enabled to glean at least suggestions as to what the mechanism may be.

Post-Mortem Examination of a Case in which Removal of the Uterine Appendages for Myoma had been Performed Three Years Before Death.

In the *London Medical Times*, August 2, 1884, Mr. Lawson Tait says:

I have just received from Dr. Saundby a jar containing the uterus of a woman, aged 47, from whom I removed the uterine appendages for a large myoma on June 21, 1881. At that time she was under the joint care of Mr. M. Hallwright and myself, for profuse menorrhagia, accompanied by intense pain. All other efforts having failed to relieve her, her health being completely destroyed and the tumor growing rapidly, I advised the operation. The tumor reached about an inch above the umbilicus, and the upper end of the incision necessary to reach the appendages was almost at that land-mark. Dr. George Fyfe, Dr. Savage, and Mr. Raffles Harmer, were present at the operation. She made an easy recovery, and never lost a drop of blood from the uterus after her convalescence, which was completed within a month. She rapidly gained strength and health, and, as she said upon my frequent visits to her, had neither ache nor ail. She happened to live close to my house, and was therefore frequently exhibited to visitors. She had been seen and examined by Dr. Marion Sims, Dr. Battey, and Dr. T. A. Emmett. Ten days ago she suddenly began to suffer from symptoms of intestinal obstruction, and as this resisted all ordinary measures, I opened her abdomen for the second time last Wednesday, July 23. Dr. P. Sydney Jones, of Sydney, Dr. Vanderwar, of Albany, and Mr. J. W. Taylor were present. I feared, of course, that the obstruction was due to some adhesion of intestine to the stumps of the for-

mer operation, but I am glad to say that my fears had no foundation. I performed enterotomy, but she survived the operation only some fifteen hours. Dr. Saundby made the *post-mortem* examination, and removed the uterus entire. The myoma has shrivelled to the size of a small orange, certainly less than a tenth of its size three years ago, and there is no trace of ovaries, or tubes, or stumps, or ligatures.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a lecture on puerperal fever which we have received from Dr. T. G. Comstock (reprint from *N. Y. Med. Times*), he says of its therapeutics:

The remedies to be named as among those absolutely requisite, that should be within reach, are *aconite, gelsemium, veratrum viride, bryonia mercurius, quinine, opium, digitalis, alcohol, nux vomica, ignatia*, and sometimes *bromide of potash*.

Refrigeration as an *auxiliary*, is proved by experience to be a precious boon, and when carefully understood and rationally applied, will be found equally useful, as when employed in scarlatina, typhus, pneumonia, and pulmonary hemorrhage. Hot fomentations in certain complications are frequently useful, and are to be recommended.

——*Godey's Lady's Book* for September presents special attractions. There are two excellent serials now running, one from the pen of the popular English authoress, Helen Mathers, called "Dreeing of the Weird." "The Story of an Elopement," by Christian Reid, has not so quaint a title, but excites scarcely less interest and admiration. The pretty other articles are not less pleasing to the general reader.

——Dr. I. H. Wood, of Denver, Col., in a reprint before us on phthisis, extols with enthusiasm Denver as a place of resort for consumptives. He writes:

"Here will be found excellent churches, schools, and theatres; and it is probably the residence of a larger number of recuperated invalids, now able to enjoy life, and take an active part in its duties, than any other city of its size in the world.

"For a winter residence it is unsurpassed, although during the summer the mountains should be resorted to, and if possible consumptives ought to camp out."

——The Proceedings of the Kentucky State Sanitary Council have been issued in pamphlet form. (pp. 60, Louisville). They contain addresses and discussions on sanitary topics, and cannot fail to be a useful aid to the progress of hygienic science in that commonwealth.

BOOK NOTICES.

The Natural Dispensatory. Containing the Natural History, Chemistry, Pharmacy, Action, and Uses of Medicines. By Alfred Stillé, M. D., LL. D., and John M. Maisch, Phar. D. Third edition, pp. 1755. Henry C. Lea's Sons & Co.

This third edition has undergone a close revision, and very extensive additions. Some idea of the latter may be had from the statement in the preface that the additional references in the index are nearly 4,000. The numerous developments in pharmacy and therapeutics which the last few years have witnessed have been carefully collated, and it may safely be said that none of them will be looked for in vain.

In the therapeutical department much consideration has been given to the physiological aspect of the action of drugs, but, as heretofore, the principal stress has been laid on their clinical features. In this respect we are glad to observe that a sounder spirit is manifested than in some modern works on pharmaceutical and therapeutic agents.

We can truthfully say that the National Dispensatory deserves its title, and is sure long to maintain its high position with the profession.

Fifth Annual Report of the Illinois State Board of Health. Springfield, 1883. 8vo., pp. 633.

This thick volume of nigh 650 pp. in small print exhibits a vast amount of labor, all or nearly all of which is sure to be remunerative to the great and enlightened state which ordered it. Few commonwealths understand the immense money value of the protection of public health. Illinois does, and within the last few months one of its greatest industries, its exportation of beef, has been saved by the excellent report made by eastern inspectors as to the enlightened care exercised over the method of preparing food of this kind.

Of the matters of general interest in this volume, we may name the small-pox epidemic of 1883, which is treated very fully in a space of 310 pages. Some excellent remarks are made in this connection in reference to the inspection of emigrants on steamship lines. There is also a full report of the medical educational institutions in the United States, their location and standing. The vital statistics are well arranged, and meteorological tables are added. The proceedings of the Sanitary Council of the Mississippi Valley are also inserted in this volume.

—Menthol has been used with success for ringworm, both in the form of a solution and pomade.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE CONTROL OF PATHOLOGICAL RESEARCH BY CLINICAL OBSERVATION.

Apropos of our recent remarks on scientific *vs.* practical medicine, we are gratified to note that the President of the British Medical Association chose the title of our editorial as the subject of his address at the last meeting of the association.

He very truly says that the study of minute organisms, which is all the rage to-day, is limited to comparatively few men, for the very good reason that the mass of the profession are too much occupied in earning their livelihoods to be able to give any time to the study of that which brings to them no pecuniary recompense. But at the same time he calls our attention to the fact that even if it is ultimately conclusively demonstrated that micro-organisms or germs are the etiological factors of disease, we must still recognize the fact that in order that they may grow and multiply, it is absolutely necessary that they should be deposited on congenial soil—that some certain conditions of the organism must exist, else they cannot work mischief. And he says:

"This predisposition may be either a general one, expressed by a proclivity in some countries, or in certain races, or in particular temperaments; or it may have been acquired by the individual either at a certain period of life, or under the influence of a variety of causes in his diet, occupation, or surroundings. Now, it is precisely with reference to these points that we can get most light—I had almost said the only light—from the general experience of the profession. A great deal of medical literature is founded on hospital practice, which, valuable as it is, wants the element of time. The floating population of hospitals passes rapidly from observation; and it is only from the medical men who have known patients for years, and often the stock from which they come, that we can get information which necessarily presupposes continuous observation spread over long periods.

"It is in respect to questions of this kind, which are so clearly within the scope of every practitioner of medicine, that I look for the best results from the labors of the Collective Investigation Committee, which, I have no doubt, will prove one of the most valuable of the agencies for good in this Association; and I am not without hope of a still larger and more ambitious effort, which will embrace not only this, but all civilized coun-

tries, in its operation; and that we may have an International Collective Investigation of Disease. From such an organization we could obtain an immense amount of information on the subject of climatic and telluric influences, and on the question of racial proclivities to disease, as well as on the important subject of diathesis.

"The subject of the proclivities of different races to disease, is one of great interest, and has been but little investigated. The facilities which the vast colonial empire of England offers for observation to medical officers of the public services, have enabled them to see much of disease in different countries of the world; and, no doubt, there is a good deal of information entombed in the *Army and Navy Medical Reports;* but we have but little definite knowledge. That the negro race enjoys a comparative immunity from yellow fever, and that even a slight admixture of negro blood brings with it a certain degree of protection from this malady, seems well ascertained. The comparative freedom of the same race from stone, and, on the other hand, their marked liability to elephantiasis, and to tetanus, are clearly made out. Again, there is reason to believe that different branches of the Aryan family present some peculiarities in respect of liabilities to morbific influence. In France, where, from the requirements of military service, statistics with respect to some classes of affections are easily accessible, it has been found that, in the provinces where there is most Teutonic blood, there is a notably greater number of exemptions from service, owing to varicose veins and hernia, than in those in which the inhabitants are of Celtic origin. On the other hand, it is considered by some that the Celtic peoples do not bear surgical operations so well. When Velpeau was reproached with the great mortality after operations in Parisian, as compared with English hospitals, he is reported to have replied that the flesh of a Frenchman was not the flesh of an Englishman."

These remarks suggest to us a great topic for observation. Within the extensive boundaries of our country are to be found all races and nationalities. It would prove most interesting investigation were each physician to keep a careful clinical history of each of his patients, and at the end of each year, reviewing his records, note carefully and publish all that occurred to him in reference to this question of predisposition.

—The International Medical Congress will hold its next meeting in Washington, in 1887.

THE INTRODUCTION OF P DEMIC DISEASE FROM EUROPE.

With the constant increase in intercourse be: tween Europe and this country, the perils which we run from an epidemic that prevails there are annually increased. The more important, therefore, becomes the Trans-Atlantic Marine Medical Service, and the more rigid should be the accountability of the steamship lines to employ competent medical officers.

It has been alleged that a good deal is wanting in this respect. It has been said that the companies, out of a mistaken policy of niggardliness, employ inexperienced and incompetent surgeons, because they are not willing to pay enough, or do not provide becoming quarters for those of proper experience and standing.

There is undoubtedly some truth in these charges, in spite of the vigorous denials of the companies themselves. Proof of it is furnished by the last Report of the Illinois State Board of Health, in the pages devoted to the Immigrant Inspection Service.

It may be considered certain that if a ship surgeon does not take care to prevent the introduction of small-pox by proper vaccination and inspection, he will not give due attention to anything else. These reports show conclusively that there was a great deal of negligence on this point in many lines. Many immigrants landed without having undergone vaccination, many reported no inspection at all, some came in with symptoms of small-pox developing on them. Some surgeons gave no cards of vaccination; in other cases, the cards bore no dates. On one steamer the inspector found 71 persons wholly unvaccinated, and this during a small-pox epidemic.

We should be justified in republishing the names of those companies and ships which thus neglected their bounden duty to the public; but we prefer to refer our readers to the above-mentioned report, where the details are given in full, the names of the surgeons and all (pp. 355–360). It is more agreeable to us to mention those lines whose surgeons had performed their duties in the most creditable manner. These were especially

the vessels of the North German Lloyd Line, and those of the White Star Line, the former to Hamburg and Bremen, the latter to Liverpool. It is to be hoped that equally thorough work will be performed on all the lines.

THE CONSEQUENCES OF THE EXTIRPATION OF THE SPLEEN.

The surgical removal of the spleen under certain conditions is to-day considered a legitimate operation. After Tizzoni had insisted upon the development of small spleen-like tumors on the omentum of animals deprived of their spleen, and after he had expressed the opinion that these new growths performed the functions of the lost organ, Prof. Mosler (*Deutsch. Med. Wochenschrift*, 22, '84) took the subject in hand, and examined into the consequences of the removal of the spleen, with the following result:

The small tumors mentioned by Tizzoni are, according to Mosler, telangieotatic-hemorrhagic lymphomas, developing from the areolar tissue of the serosa, which is rich in blood-vessels. A direct connection between the want of a spleen and these new growths does not exist.

The following phenomena were noted as the consequences in thirty cases of extirpation of the spleen practiced by Mosler.

The spleen is not essential to the life of animals.

After extirpation or atrophy of the spleen artificially produced, its function is taken up by the other lymphatic organs. In this the marrow of the bones seems to play an important part, as after the removal of the organ great alterations, similar to those observed in leucæmia, are met with for a long time. Hyperplasia of the lymphatic glands is not often noted.

The vicarious action of the other lymphatic organs seems to depend upon external influences, and is not always complete in animals deprived of their spleen, for during the first months after the removal of the organ, the blood shows an abnormal composition. This fact proves that the spleen participates in some way in the manufacture of the blood, especially in the new formation of white and red corpuscles.

The extirpation of the spleen exerts no influence on stomach and pancreas digestion, the greatly increased appetite of animals wanting their spleen being no proof of the contrary.

THE EFFECTS OF HIGH TEMPERATURE.

The remarkably exhaustive effects of a high temperature is familiar to all who have lived in tropical climates, or who have passed "the heated term" in one of our great cities. It is most perceptible on infants and the very aged. In India, the children of European settlers rarely live to adult life, and when they do, it is with relaxed bodies and inert minds.

Some interesting observations made with a view to ascertain the effect of high temperature on physiological function are reported by Dr. C. H. H. Hall, in the *Proceedings of the Naval Society*. His subjects were the water-tenders in the fire-rooms of a steamer. They are exposed to an artificial temperature of about 180° F., which is little more than the natural temperature of Southern India, where the thermometer in the sun frequently reaches 170°.

The disturbance was especially noticed on the heart's action. The cutaneous veins became turgid with blood, the pulse rose to as high as 180 per minute, and the temperature under the tongue to 103.6°. The respiration was affected only secondarily, but finally increased from 18 to 42 per minute. These striking results show how violent is the action of a heated temperature on organic function, and explain its highly injurious results in feeble conditions.

ON HYPNOTISM.

In many persons we succeed by stroking any part of the body in producing anæsthesia or rigidity in that part, without influencing the cerebral functions. Dr. Schleicher has investigated this "local" hypnotism (Annales de la Soc. de Méd. d'Anvers., 1884), and arrived at the following conclusions:

Any excitation, of medium strength or weak, repeatedly applied in a uniform and regular manner to any portion of the surface, causes insensi-

bility of that portion. According to the individual this effect sets in within a few seconds or minutes. Frequent repetition within a short time of the same manipulation makes the skin sensitive in such a degree to its influence as to produce its effect by one single stroke. Any new excitation of a different kind at once counteracts the effect of the other, and irregular stroking or rubbing forms one of these. The same peculiar phenomena may be produced in the organs of special sense. So complete amaurosis may be induced by repeated impressions on the bulbus, taste abolished by striking the tongue, smell arrested by repeated uniform air douches, diminution of the sense of hearing by repeated small strokes on the mastoid process. These effects disappear spontaneously within a few moments.

Any acute excitation besides may cause a contraction of the muscles lying below the surface to which the excitation was applied, and the same phenomenon follows direct irritation of muscles, sinews, and nerves. In the latter case the contraction affects the whole region provided by the nerve. The author finds in these phenomena a similarity between hysteria and hypnotism, and finishes his article with a speculative theory, which it is not necessary to translate.

Notes and Comments.

Rheumatoid Arthritis.

Dr. Dyce Duckworth, in opening a discussion on this subject before the late meeting of the British Medical Association, said that by rheumatoid arthritis he means an essentially chronic form of joint-disease, affecting both small and large, one or many, articulations. It may begin insidiously, with pain and swelling gradually increasing, or it may begin by more acute local symptoms. The tissues of the joint are affected by a chronic, and often progressive, inflammation, beginning first in the synovial membrane, affecting next the articular cartilage, and this, perhaps, in most cases more severely than any other texture; then the ligamentous structures; and, lastly, the ends of the bones.

While not prepared to so state positively, yet he believes that rheumatoid arthritis is distinct from, and is not evolved from, a previous rheumatic attack, since evidences of past rheumatic fever can be elicited only in a small proportion of cases, neither does he believe that it is a form of gout, considering that so far as we have gone we have established a place for rheumatoid arthritis outside rheumatic manifestations, and outside gouty disease; but he also holds that the three diseases can be correlated. With reference to treatment he says: "Whatever is good for rheumatic manifestations anywhere is, I believe, good for chronic rheumatic arthritis. The principles of treatment must vary somewhat with the exciting and determining causes in each case. Attention must be paid to the presence of any cross-taint. Little good will be gained till a better condition of general nutrition and of the nervous system is secured. All causes of exhaustion and depression must be removed. Hence, in addition to good and varied dietary, including free use of foods containing sulphur, such as onions, cruciferous vegetables, and especially mustard, a sheltered, dry, and somewhat high locality should be sought. For drugs, I like best cod-liver oil, iodide of potassium, pushed to ten or fifteen grain doses, iron, arsenic, and sulphur. Lemon-juice is well thought of, I am told, in Dublin. Counter-irritation in the early stages is much neglected, and smart blistering, Corrigan's thermic hammer, and the actual cautery, will save much subsequent trouble. Proper employment of hot sulphurous waters and of Turkish baths is, without doubt, of the highest value. For those who can afford it, I believe that a residence for some years in tropical and semi-tropical climates will often avail to prevent incurable crippling, and to arrest the disease in an early stage. I attach high importance to early treatment, exercise of the joints, and a vigorous resistance to incipient deformities. The salicylates are valuable for the worst pains at the outset, while opium and the bromides do most for the weariness of those in the advanced stage."

Imperforate Hymen—Operation.

Dr. H. E. Aust Lawrence reports this case in the *Brit. Med. Jour.*, May 3, 1884:

E. A., aged 14, was admitted to hospital on July 19, 1883, suffering from retention of menses, due to imperforate hymen. She had experienced periodical feelings of discomfort for three or four months previously, but not to such an extent as to cause her to complain, until July 13th, when severe pains were felt in the hypogastrium. The hymen was found to be imperforate and bulging, and the uterus could be distinctly felt as a hard, rounded tumour, reaching one inch above the

pubes. As the symptoms were urgent, it was decided to operate at once under the carbolic spray. The urine was drawn off, a fine trocar was pushed through the hymen, and the thick menstrual secretion allowed to drain very slowly off into a basin, placed to receive it. After some time, a piece of drainage-tube was placed in the opening, and the orifice of the vagina and the neighboring parts were covered over with a pad soaked in a solution of carbolic acid in glycerine (1 in 20); and the parts were well packed with iodoform-wool.

The dressings were changed and the urine drawn off night and morning, under the spray of carbolic acid. The bowels were kept confined for three days by opium, and then relieved by an enema; the dressings still being kept in place. The drainage-tube was taken out night and morning, and washed and replaced.

On July 26th, the discharge having ceased, the patient was placed on the operating table, and the orifice of the vagina was enlarged sufficiently to allow any discharges free exit for the future; warm vaginal injections of Condy's fluid were now used, and a plug of carbolized lint kept in the vagina for a few days, when the patient went home perfectly well, and has since menstruated normally.

Remarks.—When we consider that a large proportion of deaths from this very simple operation have been due to septicæmia, we can realize the value of treating them antiseptically. During the draining off of the menstrual secretion, air rushed in and out during each respiration; but as it had to pass through the spray, and became aseptic, no harm resulted. As it is impossible to prevent the access of air, our object must be to render it harmless, and with proper care there is no reason why perfect antiseptic precautions may not be taken. In my patient's case there was no rise in the temperature, and no bad odor with the discharges. I believe the best way to treat these cases is, to make a very small opening in the hymen, so that the fluid may drain off very slowly; and as long as there is any discharge, to maintain full antiseptic precautions.

Hypnotism.

The *Lancet*, April 26, 1884, says that the curious phenomena collectively designated by the term "hypnotism" have frequently been the subject of popular attention, more especially under the mysterious names of Braidism, Animal Magnetism, and Electro-biology. Hypnotism in a simple form is, as our readers very well know, a very old story. More than two hundred years ago the possibility of "enchanting" a hen by drawing a line before its eyes with a piece of chalk was well known, and was demonstrated to an awe-struck audience by the Jesuit priest, Anathesius Kircher. Possibly, on account of its supposed association with magic, little notice was taken of this remarkable phenomenon until about one hundred years ago, when a Swiss, Anton Mesmer, brought the subject into notoriety in France and applied it to man. In the earlier half of the present century, Mr. Braid, of Manchester, examined the matter with scientific care, and tried its curative efficacy on his patients in England; but his views met with disfavor, and the question was not taken up by the scientific or by the medical world until comparatively recent times, when a number of physiologists attempted to investigate it. Dr. Gerald Yeo, Professor of Physiology at King's College, has recently devoted some attention to the subject. We may briefly summarize the conclusions at which he has so far arrived. It is believed that the corpuscles of the grey matter of the nervous centres are called into activity by special nervous influences, which, like those affecting the muscular and glandular tissues, are associated with changes in nutrition. These nerve-regulating centres are constantly kept alive to the state of the various parts of the body, and accordingly affect the nerve-mechanisms belonging to each. When several of the more influential textures are fatigued, the entire frame is made to repose (sleep). In sleep a variety of mental and muscular acts may be performed, if certain tissues or organs remain in a state of activity (somnambulism). Without sleep, in the ordinary sense, the nervous "governors" of certain organs and parts may be thrown out of gear by notice of a special condition of the organ arriving at its nerve-regulating centre. The impulses indicating this condition (fatigue) may be counterfeited by certain variations in quantity or quality of ordinary stimulation. When local psychical arrests are thus produced without real fatigue of the organs, the surplus energy, arriving at the excito-neural centres, sets up an excessive action of some groups of corpuscles, and thus certain faculties appear exalted in acuteness.

Methods of Therapeutic Research.

This is the title of the address at the opening of the section of Pharmacology and Therapeutics of the Brit. Med. Ass., by Dr. T. J. Maclagan, in the course of which, speaking of our ability to cope with disease germs in the body, he says:

There remains the other possibility—the de-

struction of the organism in the system. This, too, is a hopeful field of research, and it is open to us. It has, indeed, been already entered on, and a new group of remedies has been suggested and given a local status as therapeutic agents under the name of germicides. Our knowledge of these agencies is at present very limited; but we may reasonably hope that in time, as we gain in our knowledge of individual germs and their conditions of life, we may also learn how to destroy them in the system. There are some, and there may be many, germicides which, while fatal to germs, are not injurious to the human body. If we could find one which was fatal to the germ of typhoid fever, but which could be taken with impunity by man, that germicide would arrest the course of typhoid fever, if given sufficiently early, before the local lesion had made much headway; and so with diphtheria, scarlatina, and all the diseases to which the germ-theory applies.

As each germ has its own special life-history, its own peculiar conditions of life, under which alone it can flourish, and its own special action on the system, it is probable, too, that each will have its own special destructive agency. An agency which destroyed the typhoid germ might have no action on that of typhus or that of scarlatina.

You are all aware that of late years much evidence has been adduced to show that the poison of the malarial fevers is an organism which is propagated in the system. It is probably by its destructive action on this organism that quinine (a recognized germicide) exercises its curative action in intermittent and remittent fevers. I believe, and have elsewhere given my reasons for my belief, that it is the same with rheumatic fever and the salicyl compounds—that the poison is malarial, and that these agencies (also recognized germicides) owe their remarkable effects in that disease to their destructive action on that poison.

Be that as it may, the recognition of the existence of such agencies as germicides, and the possibility of dealing with diseased processes, and actually curing disease, by agencies which do not necessarily have any action on the system, which act, not on the sufferer, but on that which makes him suffer—the recognition of such a possibility marks an epoch in therapeutics, and opens up to us a vast and interesting field of research, on which I hope we shall not be slow to enter, and from which great results may not unreasonably be looked for.

Cysts of Female Uretera.

The *Brit. Med. Jour.*, May 3, 1884, says:

The presence of a small cyst, projecting from the anterior wall of the vagina, and lying immediately behind the urethra, has often been detected in patients, complaining of symptoms attributed by themselves to uterine displacements. In the last number of the *Journal* reference was made (p. 827) to the researches of Dr. Max Schüller, who differs in opinion from Skene, and Dr. Kocks, of Bonn, believing that a pair of ducts situated one on each side of the female urethra, and opening at the posterior border of the meatus, close to each other, are purely gland-ducts, and not relics of the Wolffian ducts. Dr. Kocks, however, in the *Archiv. für Gynækologie*, describes the same ducts, and the occasional discharge which issues from them; he brings forward very good reasons for believing that the canals are the termination of Gaertner's ducts, the excretory canals of the Wolffian body, which is reduced in the adult female to the parovarium. When the orifice of one of these canals becomes closed, the canal itself might readily become cystic, many of the cysts that are common in other parts of the body being formed in this manner. The evidence of the Wolffian origin of these canals is not very strongly supported by teratological evidence; for though in many mammals the ducts of Gaertner open normally close to the urethra, only two cases of persistence of the ducts appear to have been seen in the human female. In one case two canals passed from the ovary downwards, opening close to the clitoris. This would support Dr. Kocks' opinion, but the case was reported by Realdus Columbus in 1559, though his absence of bias, due to ignorance of a theory unknown in his day, makes his description from certain points of view more trustworthy. In the second case, where the uterus was bicornute, a single canal ran downwards in the outer wall of the right cornu, passed down to the lower end of the incomplete vaginal septum, and then turned up, opening close to the os uteri. Professor Morrison Watson has described these cases in the *Journal of Anatomy and Physiology*, vol. xiv. More researches are required before it can be made certain that the canals made by Dr. Kocks are constant.

Urinary Paraplegia.

Dr. William M. Ord (in his address on Medicine before the British Medical Association) says: "In relation with the idea that irritation is set up in joints by irritation reflected from viscera, I am tempted to point to the so-called reflex or urinary

paraplegia as illustrating, possibly, a torpor set up in the nerve-cells of the cord, instead of an irritation dependent on centripetal irritation coming from viscera. The name reflex paraplegia, given by Brown-Séquard, has been of late replaced by a safer term—urinary paraplegia. But, whichever name we use, we recognize that an urethral irritation, most commonly dependent on a stricture, is so joined with paralysis or paresis of the lower limbs as to make it probable that the stricture is a cause of which the paraplegia is the effect. The objection—a just one—to the application of the term "reflex" lies in the fact that the paralysis can sometimes be traced to myelitis, in the lower part of the cord, sometimes to neuritis. But, in a certain number of cases, no lesion of cord or nerves has been detected, and to such cases, where the paraplegia and the urethral irritation were the only coexistences, the term reflex might be applied. I do not speak here of other reflex paraplegias. I merely wish to indicate the possibility of some such nerve-relations existing between the urethral surface of man and the joints, between the uterine surface of woman and the joints, carried on by the mediation of the nerves and cord, and to compare them with such relation as we have been treating of as probably existing between the joints and muscles through the cord."

The Relations of Physiology and Pathology.

To the mind of every thinking man, these two branches of our science hold a most intimate relationship; hence, it is gratifying to note that Dr. W. S. Greenfield chose this for the subject of his address at the opening of the section of Physiology and Pathology at the recent meeting of the British Medical Association. He very truly says: "Indeed, in some aspects, there is so much in common between the two, that there is a sort of debatable ground, which may be claimed by either physiologist or pathologist as his proper field of research. Nay, more, there are those who claim for the physiologist as his proper sphere the investigation of all phenomena of animal life, whether normally or abnormally performed. Nor are there wanting those who assert that, since the pathologist deals with those phenomena under the most varied conditions, and since what we call health is but an accidental balance of function and structure, constantly undergoing alternations and perturbations throughout natural life, he is the most capable of deciding how far structure is essential to function, and under what conditions function may be performed. But such one-sided views only serve to show that there can be no absolute severance, nor any but an artificial barrier or boundary-line, between physiology and pathology."

Vaccination with Old Lymph.

As of interest, in so far as it adds some information to the question of the efficacy of old vaccine lymph, we note that Dr. Charles F. Rideal thus writes to the *Lancet*, Aug. 2, 1884:

A short time ago I had the opportunity of testing the efficacy of some lymph collected as far back as February, 1854, by the late Mr. Robert Ceely, of Aylesbury. The contents of six hermetically sealed tubes were tried on six individuals—members of different families—and all of whom have since been successfully revaccinated with recent lymph, with the result that in every case the lymph proved itself perfectly inert. I may say that, contrary to my expectation, the lymph was in a fluid state, and had apparently lost much of its specific gravity, for it was (for vaccine lymph) particularly thin and watery. I regret that I did not carefully examine it microscopically, and that I do not possess any more.

Osmic Acid in Epilepsy.

The employment of osmic acid in epilepsy suggested itself to M. Wildermuth from the value of the drug in cases of neuralgia. At first the acid was used, but later an osmiate of potassium. The medicament was administered as pilules, each containing one milligramme of the active substance. The maximum daily dose employed was fifteen pilules, or fifteen milligrammes. Thirteen patients, the subjects of confirmed epilepsy, were under observation. The remedy was first combined with bromide of potassium, but this method was not followed by good results. Under the sole influence of the osmiate the number of attacks was steadily diminished, as compared with their frequency on expectant treatment. In only one instance, however, was complete immunity conferred.

Fæcal Umbilical Fistula.

The *London Med. Times*, August 2, 1884, reports two cases of this chronic affection, and in each instance a cure was permanently established. The treatment consisted in thoroughly clearing out the alimentary canal by purgative and enema, and then in keeping it in a state of absolute rest by the continuous administration of small doses of opium. At the same time cod-liver oil was prescribed, and the wound was left undisturbed under a pad of dry wool.

Correspondence.

A Curious Diet in Texas.

Eds. Med. and Surg. Reporter:—

In the Reporter of August 16th, is an article from the pen of C. C. Vanderbeck, M. D., Ph. D., etc., etc., having the title "A Curious Diet in Texas." After discoursing somewhat at length on the diet of various people, among others, the Esquimaux, Aborigines, Germans, the Chinese, Hottentots, Japanese, and Dirt Eaters—some of whom the learned gentleman informs us eat skunks, lizards, snakes and offal or excrement, *et id omne genus*, he adds: "But I write more especially to call attention to a custom in the far south of our country, *particularly in Texas*. There it is a common practice for the mothers to chew the food for their children, *regurgitate* and spit it out, and then feed it to them. These people are firmly set in their ways, and any remonstrance is likely to be indignantly opposed. *The bitch will often throw up her food, and then feed the vomit to her young; but doubtless many of my readers imagine in our own land, our citizens could not practice a similar custom.* Snakes and snails, rats and cats, toads and spiders, are a luxury in comparison with such diet. We scorn the diet of Australians, Zulus and Barbarians; but behold, within the jurisdiction of the Stars and Stripes, a people feed on *vomit* and chewed food." The italics are all mine. Now, sir, I have no desire to appear in print, but I wish emphatically and flatly to contradict the foregoing statement, and to denounce it as a vile slander upon as intelligent and cleanly a people, more especially as regards their food, as can be found north of "Mason and Dixon's line," or for that matter, as can be found anywhere within the domain of the "Stars and Stripes."

I have lived and practiced medicine for thirty-one years in Texas, and this is the first time I have ever heard intimated, much less charged, that any human being here ever fed even a dog, much less a child, upon the "*vomit*" of another person. It is true that, though not a *common* practice, sometimes mothers chew up food for their babes, and so feed them; but even that is not as filthy as the nursing-bottles and tubes with which Yankee shrewdness has flooded the country, manage them how you may. And I venture here to assert, without a fear of successful contradiction, that, apart from the influence of malaria, with which God has poisoned the atmosphere of many districts in the South, the children of Texas are as healthy and the mortality among them far less than in Philadelphia.

As for dirt-eating, 'tis far less common than Dr. Vanderbeck supposes. In the nearly a third of a century, I have dwelt in Texas, and with an extensive acquaintance all the while, I can safely and truthfully say I have never known a dozen of even suspected cases, and but three or four in which the fact could be established. The most ignorant classes, the most destitute negroes, are not guilty as charged, and would be as far from so living as would be Dr. V. himself. I would not be understood to be an advocate of feeding children with chewed food where not absolutely necessary, but I cannot see that the saliva of the mother is any more filthy and unhealthy than her milk; and when it is necessary to give chewed food, as is sometimes the case, I can see nothing so criminal that the mother, a nice lady perhaps, should be compared to "*a bitch.*" It is a well established fact that as a rule Southern women mature and marry sooner than their Northern sisters, and have children much faster. Hence it becomes necessary often to wean and rear the offspring by hand. Suitable other food cannot be always be had, the child cannot masticate fer itself, nor can the food always be chopped fine—comminuted—so as to be ready for reception by the stomach in any other way; hence the mother chews up and places the food in the child's mouth, but never so far as I have heard regurgitates—*vomits*—it. Nor have I ever heard in Texas of even one instance in which feeding a child upon chewed food inoculated it with syphilis. Syphilis in the rural districts and small towns of Texas is a *very rare* disease. It is doubtless more common in the cities, particularly where there are Mexicans, but of that I cannot speak positively of my own knowledge.

But I have had my say. I have set nothing down in malice. I have only tried to correct and refute what I *know* of my own knowledge to be a gross libel upon Texan mothers particularly.

Thos. M. Matthews, M. D.

Athens, Henderson county, Texas, Angust 21, 1884.

About Boils.

Eds. Med. and Surg. Reporter:

The query about the treatment and prevention of boils is perennial, and the answers are multitudinous and unsatisfactory. Bartholow says arsenic, sulphide of calcium, or phosphorus, long-continued, will bring to a stop a succession of boils; also, that a strong solution of nitrate of silver in nitrous ether is "most efficient" applied locally to the boil and adjacent territory very early. Fused nitrate of silver applied thoroughly to the center of the boil in the earliest stage is the treatment of some practitioners, but it has never been of the least use in my experience, which has been somewhat large as well as partially personal.

Other remedies which have been recommended from time to time for internal administration are alkalies, sulphur, sulphite of sodium, and tar. An old lay remedy of repute, said to have been learned from the Indians, is milk in which a bar of lead has been boiled. I have never tried this last, but intend to do so, as reports I have heard lead me to believe it has some value. Various herbs of a supposed "blood-purifying" tendency are used by the old women.

An immense number of boils afflicting us gave my father and myself favorable opportunities to experiment clinically, and we have tried all the local treatment we heard or thought of. A fly blister is extremely painful and of very little value; aqua ammonia sometimes does harm; early and deep incisions lessen the subsequent pain; collodion early sometimes influences the subsequent course favorably. Dr. Jackson, in "Letters to a Young Physician," says a crucial incision, the lines of which meet in the *exact* centre of the young boil will abort it—perhaps failure with this is due to missing the middle by a micro-millemeter; lunar caustic is a failure. In the July *Compen-*

idum of Medical Sciences is an article on the local treatment of furuncle which I believe to be more nearly a reconciliation of its pathology and clinical history than any hitherto advanced. Since receiving the the article, my attempts to utilize it have been thwarted by accidental interruption of the antisepsis.

When once one has become convinced of the futility to abort furuncle, any simple poultice may be used to promote suppuration. For my own boils I much prefer simple vaseline spread thickly on a piece of muslin. As soon as fluctuation can be felt, open deeply with a sharp bistoury, and expel the pus. Remove the core with a delicate pair of forceps soon as it is formed, and keep on the vaseline for a day longer. The crop of small pustules which spring up around the site of a large boil are best treated by the local application of spts. camphoræ, repeated on evaporation until a laver of camphor is formed.

All attempts to abort or prevent a succession of boils are unsatisfactory, though all the methods named above succeed in some cases. If the boils are your own, a course of experiments with them is interesting. If they are your patient's, put him on one-grain gelatin-coated pills of sulphide of calcium every three hours, and vaseline locally. If they still come, try phosphorus next, and after that arsenic internally. If each of these three continued for a month does no good, you are justified in trying anything else your knowledge of the physiological action of drugs may suggest. Remember that furuncle sometimes gets well without or in spite of treatment.

G. Walter Barr, M. D.

Bridgeport, Ill.

FOREIGN CORRESPONDENCE.

Medical Study in Germany.

Eds. Med. and Surg. Reporter:—

Vienna is the great, so to say, fashionable medical centre (a Scotch physician does not think his medical education complete if he has not been at least a *semester* in Vienna); here in the large court-yards of the Allgemeines Krankenhaus physicians of all parts of the world meet, almost all possible tongues are heard (I met six American female physicians during my ten weeks' stay), all come to profit by the large amount of material and hear the great teachers—if all profit is another question; those who stay but a short time do not understand the German language, or are insufficient in anatomy, physiology, pathology, etc., are apt to go away rather confused than enlightened. Courses (practical) can be taken in Vienna in all possible branches of medicine, they are from five to six weeks' duration, and cost at an average, $10 to $15 per course; any one can take part in the courses (no papers necessary), the number of students admitted in a course is generally ten to fifteen. It may happen that two to three months have to be waited before a course can be entered. The material is plentiful, therefore, the cases follow for the those who are not sufficiently theoretically posted, in too rapid succession, and tend to confuse.

The life in Vienna is much more expensive than in any of the German cities.

The regular clinics of Billroth, Nothnagel, etc., can be visited free of charge by giving a card to the respective first assistants; they are overcrowded. Billroth is the very ideal of an operator; but he speaks very little, and with a low voice, it is difficult to understand him, therefore, for those who sit a little high up.

In Berlin, also, practitioner's courses have been started some time since; each course lasts four weeks, and the number of attendants is limited to six—an advantage over the Viennese courses—the instruction is thorough and systematically, but the material is as yet rather small, as the royal polyclinic is not yet at the disposal of the privat docents, who run these courses; they have started private clinics for themselves, the faculty being opposed to the practitioners' courses, pedantically thinking that everyone ought to immatriculate for a full semester, who want to study in Berlin. The fee for a course is $7.50. The clinics of Bergmann, Martin, etc., may also be visited free of charge, for a short time, by presenting a card. Bergmann, also, is an excellent operator, and besides a good speaker and instructor. In the clinic he is perfectly at ease, no haste, no excitement, the very opposite from what your reporter in one of your journals found him to be in his private office.

Those who wish to pursue theoretical studies, and immatriculate for a full semester (any physician with a diploma can do so), best go to one of the medium and small German universities, as Leipzig, Munich, Halle, Kiel, etc., here the classes are not over-filled, the mind is not so much derivated from study as in large places, and the living is cheap. The different institutes for theoretical study are excellent; Munich has besides, the advantage of being the centre of arts, and offers, therefore, many recreations; in Leipzig is good music during the winter; Halle has magnificent new clinical structures (excellent clinic of Volkmann), and Kiel, as the smallest place, gives the best chance for quiet study, and has besides, excellent instructors, who give all possible facilities to students.

In all German clinics the same minute attention is paid to cleanliness. Operator and assistants all wear white linen coats, hands and finger-nails particular attention is paid to; also the parts to be operated upon are dressed antiseptically twenty-four hours before the operation, are shaved and cleaned. In Esmarch's clinic in Kiel, all reservoirs for antiseptic solutions, all pans and dishes for instruments, etc., are from heavy white, transparent glass, the tables are covered with heavy, polished, transparent glass plates, so that all particles of dirt may be detected; the fragility of the material does not prevent the Professor from using it.

Berlin, Aug. 5, 1884. J. H. Voje, M. D.

—Dr. W. Thornton Parker, of Fort Union, N. M., writes to the *Med. Record:* "Among the recruits lately arrived at this post is a man who was vaccinated successfully when two years of age. Soon afterward he contracted small-pox, and in May of this year was again successfully vaccinated."

News and Miscellany.

Sanitary Rights of Tenants.

The frequency with which people go to court for redress from injury suffered through poor plumbing makes the following comment of one of the New York City judges quite appropriate: "It would seem, however, from the number of cases which come before the court for determination, that plumbing is deemed exceptional in its character.

"The roof may leak, the plastering give way, the doors and windows be broken, and other misfortunes incident to housekeeping may occur, and no claim is made that an eviction has been established, or a right of action has accrued against the landlord for the tenant's ill health; but if a pipe becomes filled up (by neglect or otherwise), or if the solder becomes loosened, or the pipe itself becomes deranged, or the main sewer is in such a condition as to empty the traps, the tenant for some reason claims that a different rule applies.

"Now, if a tenant elects to hire a house which empties into a sewer, with ramifications throughout his sleeping apartments, he does so with all the liabilities that such an election engenders, and with full knowledge that no plumber has yet been able to keep out the gas or prevent the smells.

"The repairs of a sewer-pipe are not different from the repair of a window or a door, and the distinguishing injury arising from such neglect is not only incidental and remote, but as a matter of fact, is the result of the tenant's own election. He hired the premises with full knowledge of these connections, and the landlord is not chargeable with such consequential injuries as may arise from any defect that time and use produce. Under such circumstances, smells and even sickness are not only not extraordinary, but are inevitable; and I fail to see how this furnishes any ground of action against the landlord. * * * * * The charge of concealment and deception in this class of cases is undoubtedly an outgrowth of anger, which has its source from the painful effects of such defects; but the law in its present state furnishes no remedy to the tenant that I know of, and it rests with the Legislature to make landlords and builders liable in such cases, for the common law throws the responsibility upon the tenant, and I know of no provision which exempts the plumbing or the sewer fixtures from these well-settled provisions."

Over-pressure at Schools.

That the majority of city girls, the daughters of well-to-do parents are subjected to too much mental and too little physical training there can be very little doubt. In order to draw more attention to this subject, we note the following from the *Brit. Med. Jour.*, August 2, 1884:

"In his recent periodical reports on the health of Kensington, Dr. Orme Dudfield has contributed some interesting facts in connection with over-pressure at schools. In the report for June last, he observes that one out of four deaths registered from enteric fever occurred in a female child, aged eight years, whose sister, aged eleven, died on June 1, after six days' illness, from congestion of brain and convulsions. Referring to the latter death, the medical man added the following note to his certificate: 'This is the second child in my practice, within a week, whose death has been accelerated by overpressure at a board-school.' Dr. Dudfield is informed that the symptoms in both sisters were similar, so that it may be a question whether both cases were not of the same nature. An earlier report contained an account of the death, under peculiar circumstances, of a school girl, aged twelve. Feeling unwell, she was sent home; and on the next day was taken to one of the so-called 'dispensaries,' a doctor from which attended her at home until she died. This doctor refused to certify the cause of death, and an inquest was called for; the result of the post-mortem examination resulting in a verdict of death from typhus. It is possible, however, as Dr. Dudfield observes, that the child may have died from brain-trouble, *e. g.*, meningitis. Her father stated that she was much excited and anxious in connection with an approaching school examination, and that, until she became delirious on the third day preceding death, she was constantly engaged in calculations, recitations, etc, Curiously enough, after the report was in type, Dr. Dudfield received notice of the death of a girl of the same age (12), a pupil at a board-school, from 'over-application to study: meningitis.' Dr. Dudfield adds, as worthy of mention, that, some few years ago, the death of a young lady was certified as typhus, which, after careful inquiry, he satisfied himself was really due to over-application to study, leading to meningitis."

Sanitary Paving of Streets.

The following suggestion from the *British Med. Journal* is worthy of reproduction:

"At the present season, when the imperative necessity of immediately removing anything that may contaminate the atmosphere, or serve as a medium for the dissemination of the germs of disease, is fully recognized, it is not much to be desired that our streets, and especially our back streets and slums, should be more generally paved with some material, such as asphalte, which, being non-absorbent and impervious, cannot retain any liquid impurity, while its perfectly smooth and level surface is not only washed down by every shower of rain, but offering no obstruction to the free action of the broom, is kept perfectly clean with the greatest ease, preserving the atmosphere in a sweet and wholesome condition?"

A Woman Resident in the Philadelphia Maternity Hospital.

At a recent meeting of the Obstetrical Staff of the Maternity Hospital the following resolution was unanimously adopted: "*Resolved*, That the Obstetrical Staff of the Maternity Hospital desire, if agreeable to the Board of Governors, that a female resident physician be appointed to serve in the Maternity Hospital, the length of term to be regulated by circumstances, not longer than one year." This resolution was presented to the Board of Governors at their regular monthly meeting, held August 26, at the hospital, when they unanimously resolved

1. That the Maternity Hospital should have a resident physician; and,
2. That the resident physician must be a woman.

Items.

—Mr. Thomas Jones reports in the *Lancet*, Aug. 2, 1884, a successful extirpation of the larynx for epithelioma.

—In the *Medical Record*, August 16, 1884, Dr. C. C. Stockard reports a fibro-cyst of uterus weighing one hundred and thirty-five pounds.

—In the *Lancet*, August 2, 1884, Mr. Charles N. Macnamara reports a case of obstruction of the œsophagus successfully treated by gastrostomy.

—The true use of a porous plaster, according to a Milwaukee druggist, is "to retain the back in its proper place and let the pain crawl out through the holes."

—In the *British Med. Jour.*, Aug. 9, 1884, Dr. W. A. Meredith reports fifty cases of completed ovariotomy, with brief notes of nine other cases of abdominal section.

—In a case of mammary cancer in a young married woman in the fifth month of pregnancy, MM. Trélat, Polaillon, Terrillon, Guéniot, and Verneuil all advised immediate operation.

—"So you prefer my medicines to those of Dr. Pillsbury, Mrs. Mulligan?"

"Och, indade, dochter dear, ye're a deal better than th' other ould humbug."

—In the *Lancet*, August 2, 1884, Dr. Judson S. Bury reports a case of congenital contraction of the orifice of the pulmonary artery from fusion of the valves; foramen ovale open.

—The Queen of England has appointed Sir Prescott Gardiner Hewitt, Bart., F. R. S., to be one of her Majesty's Sergeant-Surgeons in Ordinary, in the place of the late Mr. Cæsar Hawkins.

—An eburnated exostosis of the frontal bone, filling up the orbital cavity, has been removed by M. Badal by means of mallet and chisel, healing taking place without damage to the eye or vision.

—Boegehold reports a case in which, during the removal of a malignant tumor of the neck, the thoracic duct was opened. Simple compression controlled the escape of chyle, and the wound did well.

—Gastrostomy, Radical Cure of Hernia, and Thyroidectomy, was the title of Sir William MacCormac's address at the opening of the section of Surgery at the last meeting of the British Medical Association.

The *Glasgow Medical Journal*, for August, 1884, contains an excellent article by Dr. George S. Middleton, on the pathology of pseudo-hypertrophic muscular paralysis, with remarks on a so-called degeneration of the nervous system.

—A preliminary meeting has been held, and the necessary steps taken, for the formation in Glasgow of a Society for the Prevention of Cruelty to Children. It is to be on the same basis as those already existing in London and Liverpool.

—The *Therapeutic Review* says, "Methyl salicylate (oil of winter-green), mixed with an equal quantity of olive-oil, or linimentum saponis, applied externally to inflamed joints affected by acute rheumatism, affords instant relief, and, having a pleasant odor, its use is very agreeable."

—The first factory in Scotland for the manufacture of ice has been established at Hogganfield, near Glasgow. The ammoniacal process is the one that has been adopted, and the ice is to be frozen from filtered Loch Katrine water. The increased demand for pure ice, in health as well as in sickness, and the difficulty of obtaining it free from organic impurities, marks this as an undertaking of considerable importance and public utility.

—Prof. Da Costa teaches that in the early stages (before contraction) of interstitial hepatitis (cirrhosis), a cure may be effected, but that after contraction nobody ever recovered. He has seen the disease in women who did not drink, and the worst case he ever had was in a boy four years old, in which the diagnosis was confirmed at the autopsy. Inherited syphilis is a cause of it. In the early stages the remedies are leeches, sulphate of magnesium, cream of tartar, iodide of potassium.

QUERIES AND REPLIES.

In answer to the query of M. S., in REPORTER for August 9, I have used pills of calcium sulphide gr. $\frac{1}{10}$ t. i. d., with excellent result. Yours truly, SPENCER M. FREE, M. D.

EDS. MED. AND SURG. REP.—

What is the best treatment for gelatinoid polypus? Would like to have opinions through the columns of the REPORTER from the profession. S. M., M. D.

MARRIAGES.

EAKIN—TEVIS.—In Philadelphia, on July 31, by Rev. Matthew Newkirk, D. D., Dr. A. Louis Eakin and Margaret W. Tevis.

HANES—STONE.—At St. Paul church, Cincinnati, Ohio, July 23, 1884, by the Rev. Daniel Benedict, D. D., Dr. J. C. Hanes, of Wyoming, Iowa, to Miss Eunice A. Stone, of Cincinnati.

KING—BUTLER.—In New York, Thursday, August 7, by the Rev. Henry Chamberlain, Oliver R. King, M. D., to Mary W., daughter of Henry Butler.

RISHEL—ARMSTRONG.—June 18, by Rev. T. R. McDowell, George P. Rishel, M. D., of Bellefonte, Pa., and M. Louise Armstrong, of Fair Hill, Md.

DEATHS.

BARNES.—In St. Louis, July 15, A. F. Barnes, M. D., after a long and painful illness, in his 58th year.

BEARD.—In Evansville, Ohio, July 26, of lockjaw, after a short illness, Dr. S. C. Beard, aged 35 years.

CHANDLER.—In New Orleans, July 18, 1884, Dr. Wm. S. Chandler, aged 74 years, a native of Hopkinton, N. H., and a resident of New Orleans for the past forty years.

DAYHUFF.—In Kokomo., Ind., July 22, Dr. And. F. Dayhuff, aged 57 years.

PARRISH.—Of paralysis, in the county of Goochland, Va., on the 4th inst., Dr. Robert G. Parrish, in the 76th year of his age.

VALENTINE.—At Lucerne, Switzerland, on Thursday, August 7, 1884, Samuel M. Valentine, M. D.

WEBSTER.—In St. Louis, Dr. A. W. Webster, July 30, in the 77th year of his age.

WOODWARD—In Philadelphia, Pa., suddenly, on August 17, Dr. Joseph Janvier Woodward, U. S. Army, in the 51st year of his age.

FRENCH THEORIES ON CHOLERA.

BY M. LEREBOULLET,

Of the Paris Faculty.

The question of the day before the French Academy is cholera at every point of view. Among the most important communications are those on prophylaxis of the disease by M. Noël Gueneau de Mussy, which have their foundation in the similarity of propagation of typhoid fever and cholera.

It is very evident that the French savants have keenly felt the discovery by the German professor, Koch, of a microbe, special to the disease, in the intestinal dejections of choleraic patients, after the scientific envoys of M. Pasteur to Alexandria had asserted that none such existed.

In a recent article on the subject, M. Lereboullet, of the Paris Faculty, very largely considers this part of the subject.

MM. Straus and Roux have studied at Alexandria and Toulon the pathological anatomy of cholera. They found that the lesions observed were identical in both epidemics. They have sought to discover, with the greatest care (and their competence in such research is undeniable), if there existed any microscopic organism which might be considered as the specific infectious agent of the disease and they have failed to find any such bacillus or microbe.

Well acquainted with the works of Prof. Koch, having assisted in his researches, using the same reagents, they have, like him, found that in the intestinal dejections of individuals dying of cholera there existed a microbe of special dimensions and form. But, on the other hand, they have found that this microbe was not always present; and, again, that it could be found, not only in cholera, but also in ordinary dysenteric dejecta (malassez), in the vaginal mucus of women suffering from leucorrhœa, and in the uterine secretions of a woman having epithelioma of the os.

These observations would seem to prove that the exterior form of a microbe is not sufficient alone to characterize it, and that in the absence of direct proof, which might result from a fertile inoculation, the affirmation of M. Koch must be received with a certain amount of reserve. One fact is of very great importance, and that is the very rapid multiplication and constant appearance of these bacilli in the intestinal mucus of subjects dying very suddenly from cholera.

If, as has been asserted, a large number of these microbes be found in the intestinal mucus rapidly taken from the subject just after death from the disease, and if these special microbes described by Prof. Koch are also found later in the course of the malady, it may be possible that they constitute the infectious agent in the disease.

But whatever be the value of this pathologic discovery, it must be admitted, that of all the maladies possessing elements of contagion and infection, cholera, in its modes of evolution and transmission, appear most compatible with the hypothesis of causation by an animated germ or microbe.

If it be proven later that Prof. Koch has been mistaken as to the form and nature of the bacillus described by him, it is probable that some other

observer may discover a characteristic element remaining fertile after several cultures.

What remains demonstrated, and has even been admitted by M. Jules Guerin, is the transmissibility of the malady, or, in other words, its contagiousness, a fact established by a number of well-authenticated observations.

But if, as has been admitted, cholera is transmissible from the sick to those in health, it is no less proven that the elements of contagion are contained in the choleraic dejections, that is in products elaborated in the intestine, rich in infectious germs, and, whether or not the doctrine of Pettenkofer be admitted, susceptible of reproduction in the soil where such dejections are deposited. After such reproduction, these germs undubitably acquire greater virulence, and transmit the malady through drinking water and by means of alimentary products, on which they may be deposited.

If the truth of these assertions be recognized, it appears difficult to admit any points of resemblance between this very grave epidemic disease and the cases of sporadic cholera or cholera morbus which occur during the hot months. M. Ernest Besnier has presented a very clear exposé of this part of the subject.

At a clinical point of view, cholera morbus, or cholera nostras, as it is sometimes called, may present, in certain very exceptional cases, some analogy with Asiatic cholera. But it never kills within a short period of time a large number of individuals, as does the other. From 1875 to 1883 it caused but 120 deaths at Paris out of a population of 2,300,000; that is, only about 14 each year. Again, this summer cholera attacks at the same time many cities more or less distant from each other: it does not invade successively one city after another where individuals have arrived, in apparent health, from the city first affected.

Epidemic cholera breaks out suddenly in a city after the arrival of a vessel from an infected port, or soon after the introduction of germs, imported by individuals coming from a city already attacked by the epidemic.

Epidemic cholera, causing in a short space of time numerous deaths, has never been spontaneously developed in a city far from the seaboard, like Paris, Vienna, or Berlin. In every epidemic the malady has raged for a certain length of time in the seaports before appearing in these central cities. The fact that the disease seems to appear simultaneously in different parts of the city, does not prove that it was not originally the result of contagion.

As regards the present epidemic, the cholera which first took root in one quarter of Toulon (La Division), did not appear at Marseilles until after the arrival in the latter city of individuals emigrating from Toulon, and at the commencement of the epidemic the first cases were traced to two places from which they originally started. The same observation was often made in anterior epidemics. It will suffice to prove this to read the instructive memoir contributed by M. Jules Worms to the *Gazette Hebdomadaire* in 1865.

But even when the direct filiation of all the cases related cannot be established, a few negative cases will not suffice to offset the great number of positive facts, which demonstrate that the epidemics follow one on the other, and that it was possible in 1865, as in the preceding epidemics in 1822, in 1830, and in 1846, to follow, step by step, the progress and extension of cholera.

M. Jules Guerin has very ably attempted to demonstrate that cholera is often developed spontaneously in the large cities, where it appears in the same manner as summer cholera; but, if he considers the history of anterior epidemics, he will find it difficult to escape the fact that their course and importation from city to city has been distinctly traced. And if he recognizes this extension as occurring in any one epidemic from one place to another, how can he reconcile this fact with the doctrine he has attempted to demonstrate, of the identity of epidemic cholera with the cholera morbus of the hot months.

We repeat what we have already said regarding the very rapid progress of the disease, which has swept away so many victims at Toulon and Marseilles. "If it be admitted that the choleraic germ is developed in the intestines and transmitted by the dejections, it can be very readily understood how different quarters of the same city may appear to become infected at the same moment. It is generally admitted that at the debut of the epidemic, some of the individuals affected are at first, during the period of prodromic or premonitory diarrhœa, able to be about and attend to their usual occupations. By such patients several quarters of a city might be almost simultaneously infected through the water-closets and sewers into which their choleraic discharges find their way. Another source of rapid spread of the disease would be by provisions coming from infected houses.

"If it be necessary to reject, in part, the telluric theory advanced by Pettenkofer, as it explains neither the epidemics developed on board ships, nor the transmission of cholera by cloth-

ing and merchandise, still he may be in the right when he asserts that the choleraic germ, in order to become noxious and infectious, has to undergo certain transformations similar to those observed in animals of alternating generations? This doctrine, if true, would explain why direct inoculation of the disease has been attempted in vain. It explains, also, the sterility of the germs collected by Koch and cultivated in liquids, perhaps, unfavorable to this transformation."

Perhaps this theory would also account for the fact that the cholera seems to disappear in Provence and in Italy without attacking the large cities, which are better cared for, at a hygienic point of view, and therefore do not offer a soil so favorable for the production and propagation of the infectious germs.

We have already remarked, when citing the proportion of deaths in anterior epidemics, that, like most exotic diseases, which seem to gradually become extinguished in places which have been several times attacked, cholera diminishes in gravity. The epidemic of 1873, which was certainly imported from without, disappeared after attacking several cities of Normandy and Paris, where it caused but 855 deaths. It is to be hoped that such may be the case for the present epidemic. That the disease has not already attacked Paris and other northern cities, notwithstanding the numerous ways of communication and the absence of prophylactic measures, must undoubtedly be due to the vastly improved hygienic conditions in all the large towns.

COMMUNICATIONS.

METRICAL ANATOMY.

BY JOHN M. WHITE, M. D.,
Of Pleasant Ridge, Ala.

THE EYE.

The antero-post. diameter of the eyeball is about an inch, and exceeds the transverse by about one line. The segments of the larger sphere forms about $\frac{5}{6}$ of the globe, and the smaller shere forms the remaining $\frac{1}{6}$. The cornea forms the anterior $\frac{1}{8}$ of the globe, and is 10 to 11 mm. in diameter. "It is not quite circular, being a little broader in the transverse direction." The larger ciliary processes are each about "$\frac{1}{10}$" of an inch in length. The circular fibres of the iris form a band about "$\frac{1}{30}$ of an inch" in width. The ciliary ligament is about $\frac{1}{40}$ of an inch thick. The ciliary muscle is a circular band about $\frac{1}{8}$ of an inch broad on the outer surface of the fore part of the choroid. The optic nerve enters the retina about $\frac{1}{10}$ of an inch to the inner side of the yellow spot. The lens is $\frac{1}{3}$ of an inch in the transverse diameter, and its anterior-post. diameter $\frac{1}{4}$ of an inch, and is about this distance behind the cornea. The canal of Petit is $\frac{1}{10}$ of an inch wide.

THE EAR.

The auditory canal, from the bottom of the concha to the membrana tympani is an inch and a quarter in length, "is curved upon itself so as to be higher in the middle than at either extremity." The cartilaginous portion is about $\frac{1}{2}$ an inch in length, and the osseous portion is about $\frac{3}{4}$ of an inch in length, and narrower than the cartilaginous portion. "Its inner end is smaller than the outer," being 7 to 9 mm. in diameter. "The anterior wall projects beyond the posterior about 2 lines."

THE MIDDLE EAR.

The cavity of the tympanum measures about 5 lines from before backwards, 3 lines in the vertical direction, and between 2 and 3 in the transverse, being a little broader behind and above than it is below and in front." The Eustachian tube is from an inch and a half to two inches in length. "The osseous portion is about $\frac{1}{2}$ an inch in length," and at its lower end it is 2 to 3 mm. in diameter. The cartilaginous portion is about 1 inch in length. Its canal is narrow behind, wide and expanded in front, terminating by an oval orifice at the upper part and side of the pharynx, behind the back part of the inferior meatus. Where it opens into the pharynx, it is perhaps 4 mm. or more in diameter, but it is capable of dilatation or contraction.

THE INTERNAL EAR.

"The vestibule measures about $\frac{1}{5}$ of an inch from before backwards, as well as from above downwards, being narrower from without inwards." The semi-lunar canals measure about $\frac{1}{20}$ of an inch in diameter, and the ampulla measures a little more than $\frac{1}{10}$ of an inch. "The cochlea measures about a $\frac{1}{4}$ of an inch in length, and its breadth towards the base is about the same." The spinal canal is $1\frac{1}{2}$ inches in length along its outer wall. The commencement of the canal is $\frac{1}{10}$ inch in diameter. The membranous semi-circular canals are about $\frac{1}{3}$ the diameter of the osseous canals.

In tenotomy of the tensor tympani the knife may be passed about 3 mm. into the tympanum.

THE NASAL FOSSA.

From floor to roof of nasal fossa measures about 4 cm. From near anterior nasal spine at margin

of the anterior nares to front part of inferior turbinated bone, is 15 to 17 mm. From anterior nasal spine to post-nasal spine is 5 cm. From lower lateral margin of anterior nares near anterior nasal spine to lower lateral margin of the post nares is about 5 cm. The two anterior nares will measure 25 mm. in the transverse direction at the lower part, measuring across the post-nares from one hamular process to the other, it is 3 cm. "Each aperture of the post-nares measures about an inch in the vertical, and half an inch in the transversal direction." The anterior palatine canal is 3 to 4 mm. within the margin of the nares. From post-nasal spine to bony opening of the Eustachian tube is 45 mm., and it is 20 mm. from post-nasal spine to where the Eustachian tube opens into the mucous membrane of the pharynx.

THE MOUTH.

From the incisor teeth to post-nasal spine it is 52 mm. The post-palatine canal is 14 to 15 mm. deep and 2 to 3 mm. in diameter. One is sometimes larger than the other. They are situated 5 cm. from the incisor teeth. From canine tooth of the opposite side to the osseous opening of the Eustachian tube is 90 to 93 mm., and from same tooth to membranous opening of the Eustachian tube it is 65 mm. From incisor teeth to tip of the hamular processes is 55 to 56 mm. The hamular processes are 2 cm. from the post-nasal spine. "The duct of the parotid gland is about 2½ inches" in length and about 1 mm., or a little more, in diameter. Wharton's duct is 2 inches in length.

"THE PHARYNX

is about 4½ inches in length and broader in the transverse than in the antero-posterior diameter."

THE ŒSOPHAGUS

is about nine inches in length and its coats about 2 to 3 mm. in thickness. A knowledge of the distance from the incisor teeth to hamular processes and post-nasal spine is useful in the operation of staphyloraphy. The hamular processes project below the margin of the hard palate very near 1 cm., and sometimes not beyond 8 mm.

BASE OF THE SKULL—EXTERNAL SURFACE.

The vidian canal is about 9 mm. deep and less than 1 mm. in diameter. The pharyngeal spine is 33 mm. from the posterior nasal spine. The foramen ovale about 4 or 5 mm. in diameter transversely is 3 cm. from the tip of the hamular processes and about 21 mm. from tip of the external pterygoid process. It is 8 or 9 mm. from its inner side to the outer side of the foramen lacerum medium at vidian canal. About 4 or 5 mm. behind the foramen ovale is the foramen spinosum it is nearly 1 mm. in diameter and 6 mm. in depth. The spinous process of the sphenoid is about 23 mm. from the vidian canal, and the vidian canal and foramen lacerum medium is 34 mm. from the posterior nasal spine. The styloid process at its middle is 44 to 45 mm. from the hamular process, and is 10 mm. from the lower margin of the ext. auditory canal. It is "about an inch in length," and varies in size and shape, and is 14 mm. from tho spinous process of the spheroid. The styloid process is 45 mm. from the hamular process, and 3 cm. from tip of external pterygoid process, measuring from its base. The stylo-mastoid foramen is 1 mm. or a little more in diameter. The foramen lac. medium is 8 mm. in its transverse diameter, and 2 cm. from same foramen of the opposite side, and 12 mm. from upper and posterior part of the vomer. The carotid canal is 7 mm. in diameter and 12 mm. in depth and its inner edge is 15 mm. from the foramen lac. medium. It is 5 to 6 nm. from its anterior margin to the osseous opening of the Eustachian tube, and 11 mm. from nearest part of the foramen ovale. It is 10 mm. from base of the styloid process. The vidian canals are 35 mm. apart. The foramina ovale 55 mm. apart. The foramina spinosum 65 mm., and the osseous opening of the Eustachian tube 60 to 62 mm. apart. The carotid foramina are about 55 mm. apart.

THE ZYGOMATIC FOSSA AND SPHENO-MAXILLARY FOSSA, ETC.

Twenty-five mm. is the distance from the zygoma where it articulates with the molar to the surface of the sphenoid just above the pterygoid ridge, measuring in a horizontal direction, but the distance varies somewhat, not being the same on both sides. The foramen ovale is 45 mm. from the zygoma, where it articulates with the molar. From same point on zygoma to surface of external pterygoid plate near its root is 37 to 42 mm. It is about 42 mm. from the zygomatic articulation to the lower part of the pterygo-maxillary fissure. From zygomatic articulation to inner wall of the spheno-maxillary fossa is 45 to 47 mm., though there is a slight difference in depth in the two sides. From under part of zygoma where it articulates with the molar to external opening of the foramen rotunda is about 37 mm. The foramen rotunda is 4 to 5 mm. in depth, and from same point to external opening of the vidian canal it is 46 mm. (See REPORTER, February 23, 1884.)

Correction.—The infra-orbital canal is about 12 mm. in depth to where it ceases to be a canal, and

measuring through it to the spheno-maxillary fissure it is about 25 mm., and not 17 mm. in depth as stated before. The depth and size of this canal should be considered in the operation of gouging out the second branch of the fifth nerve for cure of neuralgia. The foramen magnum is 4 cm. antero-posteriorly, and 3 cm. in its transverse diameter, measuring from just behind the condyles. Its anterior margin is 43 mm. from the posterior nasal spine.

REMARKS.

The above measurements are for the adult—they vary, of course, in different individuals somewhat. They do not *vary*, however, more than the measurements of different pelves, and they will, I hope, be of service to the surgeon as pelvic measurements are of service to the obstetrician. If people generally knew that the distance from the bottom of the concha to the membrana tympani is only $1\frac{1}{4}$ inches, perhaps they would not so often rupture this membrane by introducing hairpins, etc., too deeply into the ear. A knowledge of the metrical anatomy of the eyeball, and the distance to the lens may be useful in the operation of removing cataract. The metrical anatomy of the nasal fossa will show to the surgeon the size to make his plug in the operation of plugging the posterior nares; it will aid him in removing foreign substances from the nose, and in introduction of the Eustachian catheter. A knowledge of the metrical anatomy of the base of the skull, its foramina, and their metric relations to the pharynx, may be useful to the surgeon (as the distance from the posterior nasal spine to the anterior margin of the carotid foramen is 56 mm., or 5 cm., and the posterior margin of the carotid foramen is 43 to 45 mm. from the tip of the hamular process). If he deems it practicable to make compression on the internal carotid artery at the carotid foramen in case of wound of this vessel, it may aid in the operation of division of the second branch of the fifth nerve for cure of neuralgia, by showing the depth of the zygomatic fossa, and by showing the metrical position of the styloid process; it may be useful in operations on the parotid gland. The thickness of the walls of the pharynx should be noticed in the operation for stricture of it.

ON MEMBRANOUS CROUP.*

BY R. W. HUTCHESON, M. D., M. R. C. S.,
Of Queen's County, N. Y.

I will briefly relate the particulars of a case which recently came under my care. It is that of a girl, aged 13, residing at the village of Baldwin. About three weeks previous to her illness she suffered from a severe sore throat, which was attended with fever, enlargement of the glands of the neck, white patches in the throat, and fœtid breath. As the mumps were prevailing in the neighborhood at the time, her friends came to the conclusion that she was suffering from that disease, and consequently did not seek the advice of a physician. The girl, however, was kept within doors until the 11th of March, when, although still suffering from general weakness, she persuaded her mother to allow her to go to Sunday-school. In consequence of the exposure, she was taken seriously ill that night with fever, hoarseness, and dyspnœa, and was unable to sleep. She was no better on the following day. On Monday night, March 12, she became so much worse that her friends thought she would die before morning. I saw her on the 13th. I found her sitting up, being unable to lie down; her countenance was pale and somewhat bloated; temperature, 102; pulse small, weak, 120 in frequency; respiration, 30. Her voice was husky and almost suppressed; there was a frequent cough, which was dry, brassy, suffocative; in other words, croupy—a sound somewhat difficult to describe, but when once heard, can never be forgotten. The tonsils were congested and enlarged, and indentated from previous ulcerations. There were also numerous white spots scattered over them, about the size of duck-shot, which were evidently of recent date. The tongue was coated; bowels regular; urine free from albumen.

I ordered the patient to be put into a warm room with a temperature of 75° F., and that the air should be saturated with steam. I also directed the patient to inhale steam from lime-water for twenty minutes every two hours, unless she should sleep. This had a salutary effect. It moistened the air-passages, thinned the secretion, and thus enabled the patient to expectorate more easily. The medicine prescribed was twenty drops of the balsam of copaiba, with glycerine and gum, taken every two hours. Her diet consisted of beef-tea and a liberal supply of milk.

In consequence of this plan of medication the more urgent symptoms were arrested, and continued so until Thursday morning, March 15, when, after a severe paroxysm of coughing, the patient was seized with a violent fit of suffocation; after which, the dyspnœa increased and became more noisy. These attacks were renewed in frequency and violence, the patient becoming

*From a paper read before the Queen's County (N. Y.) Medical Society.

almost black in the face, and each fit of suffocation threatening a speedy dissolution.

The girl was now very restless; beads of perspiration covered the skin, and each muscle of respiration was exerting itself to draw air into the lungs. The neck thus appeared elongated, and the supra-sternal region hollowed out; while the epigastric region was drawn in, the lower ribs collapsed and the respiratory murmur suppressed.

It was thus evident to all present that unless some relief could be obtained the girl could not survive many hours. I, therefore, suggested tracheotomy as a dernier resort. I explained the operation to the patient and friends, who at once consented to have it done—the girl, now fully realizing her condition, nodding assent thereto.

I procured the services of my friend, Dr. G. Hammond, of Freeport, who very kindly assisted me. Chloroform was administered, but not in sufficient quantity to produce complete insensibility. I had very little difficulty in making the incision and introducing the canula. The relief was immediate, the friends at once exclaiming, "How easily she breathes." The relief was visible to all.

For four days we found that by closing up the outer orifice of the canula no air could pass through the larynx; but on the fifth day, after hawking up some hard lumps, the air passed readily, and on the sixth day after the operation I removed the canula, and closed the wound. The wound healed very readily, and the patient made a rapid recovery.

I might mention that several of those who sat up with the girl and assisted in nursing her, were taken down with fever and sore throat with white patches, thus showing the infectious nature of the disease.

This is a case of common occurrence; every practitioner of medicine is called upon to treat cases of this description every year. Although generally very unsatisfactory to manage, they are nevertheless very interesting cases. Take, for instance, the diagnosis: Under what nosological head would you put the above-mentioned case? Some of you would say, Why, it is a case of croup; others, No, it is laryngitis; while probably those of you who are acquainted with the latest writings on the subject would call it diphtheria. The poet says that a rose would smell as sweet with any other name. So we find that in this case the pathological condition is the same whether you call it croup, laryngitis, or diphtheria, to wit, an inflammation of the larynx, leading to the formation of a pseudo-membrane, which, acting mechanically, prevents the access of air into the lungs, thus causing asphyxia.

It may be mentioned once for all, that these remarks have no reference to what is called catarrhal croup, or catarrhal laryngitis, which is generally a simple affair, and only proving fatal through the grossest neglect and bad management. It is generally more sudden in its accession, and is attended in a marked degree with what is called a neuropathic element, namely, spasm of the muscles of the larynx. The cough in catarrhal croup is therefore more sonorous, with less of the metallic ring about it than in that of the more formidable pseudo-membranous variety. Emetics, too, act very differently in the two diseases: they are specific in the one case, while they are dangerous in the other, and generally lessen the chance of recovery.

You are all familiar with the fact that at the present time there is a sharp controversy going on among pathologists and physicians with regard to the identity or non-identity of the pseudo-membranous croup and diphtheria. On the whole, it appears that the former theory is gaining ground; and accordingly we find that in the more recent works on the Practice of Medicine (Bristow's, for example), the two diseases are classed under the same head.

Without going very deeply into the controversy (for you are all familiar with the subject), let me mention briefly one or two points that have been brought forward in opposition to the theory that they are identical.

First. It is argued by some that diphtheria is a blood disease, and pseudo-membranous croup only a local trouble. This, I conceive, is a distinction without a difference. We are all familiar with the fact that diphtheria more often kills by asthenia than by apnœa; and yet, when a membrane does form in the larynx in a recognized case of diphtheria, has any one been able as yet to point out any difference between that membrane and the one formed in an ordinary case of pseudo-membranous croup?

It is my firm conviction, after some years of observation and study, that whenever we have an inflammation of pharynx or larynx, which is attended with the formation of a pseudo-membrane, the affection may be set down as due to diphtheria. And I think if you would investigate all the cases of pseudo-membranous inflammation of the larynx, which come under your observation, you will find that if there are not unmistakable signs of diphtheria present, you will ascertain, in

the majority of the instances, a distinct history of a previous attack in the patient himself or some members of his family. In some instances the attack is so slight as to escape the observation of the patient or his friends. This may seem a strange remark, but it is nevertheless a fact. I have attended families ill of diphtheria, where one or more members were suffering from it in its malignancy, while the others had it so slightly as to cause no complaint from the patient, and the disease was only discovered upon inspection of the throat. I have often, too, been able to make my diagnosis in the case of a patient suffering from croup, when no membrane was visible, by examining the fauces of other members of the family, and there I have discovered sufficient evidence of the disease in the presence of diphtheritic patches.

Secondly. It is said that croup is a sporadic disease, while diphtheria prevails epidemically; and also that the latter is infectious, and the former not. This is certainly not a fair distinction, for the formation of a membrane in the larynx is but an occasional manifestation of the diphtheritic poison. If the membrane always formed in the larynx is diphtheria, then indeed the one would be as epidemic as the other. But, is not croup more prevalent during and after epidemics of diphtheria? How often do we witness a solitary case of malignant diphtheria occurring in the midst of a family of children, and all the rest escape? And how often have we seen two or three children in a family die, within a few days of each other, with all the symptoms of pseudo-membranous croup?—no fœtid breath, no enlargement of the glands of the neck, no asthenia.

Thirdly. It is observed, further, that in pseudo-membranous croup there are none of those after-symptoms called sequelæ, paralysis, and cutaneous complications for example, which we so often observe after diphtheria. Dr. Jacobi hits the nail on the head in reference to these when he says that "it was for the very simple reason that very few patients sick with croup lived until they could become paralytic," and "that he had seen the wound, after tracheotomy, in cases of supposed croup, covered within twenty-four hours with a diphtheritic exudation; and it was a fact well known that when blisters were applied in the treatment of croup the vesicated surface might become covered with a membranous exudation." (See *Monthly Abs. Med. Science.*)

Fourthly. There is one other so-called distinction to which I might refer, namely, the presence of micrococci in diphtheria and their absence in pseudo-membranous croup. I think, however, that future investigations will show that these microscopic objects are always to be found in the atmosphere. Indeed, Dr. Lewis Smith and others assert that they have observed them on the gums and between the teeth in healthy persons, as well as in all inflammatory exudations of the fauces. Such a distinction, therefore, cannot hold good in point of fact. Nevertheless. it does seem highly probable that future researches will demonstrate, if, indeed, the evidence already obtained be not conclusive, that the rapid increase and migration into the blood and tissues of the body, of bacteria, is the chief, if not the real, cause of the malignancy of diphtheria.

Those of you who are familiar with the history of the "trichinous disease" will not consider this an unreasonable hypothesis. You are aware that in this disease the parasites gaining access to the mucous membrane of the alimentary canal rapidly increase in number, and at once migrate into the muscles of the body, thus causing the most alarming symptoms, and in many cases death itself. But the whole subject of bacteria is still *sub judice.*

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA,

BY WILLIAM GOODELL, M. D.,

Prof. of Gynæcology in the University of Pennsylvania.

(*Concluded from page* 261.)

In this case we are having rather more hemorrhage than usual. The cancerous cachexia is well marked, but you will not always find it so. Remember, that a clear and even florid complexion is not an indication of the absence of cancer. As far as the operation is concerned, I think the cases in which the cachexia is most marked are the ones most favorable for operation: that is, I think the operation does them more good, and the reprieve from death is longer. The reason of this is that women with florid complexions have so much blood that the parts are succulent, the fungous mass very soft and hemorrhagic, and the disease sooner returns.

Having torn away all I can with my fingers, I inject pure vinegar, and now resort to the serrated curettes. With these the parts are thoroughly scraped, and with the gouge-forceps the vaginal portion of the cervix is removed. Next, with the platinum buttons of the thermo-cautery, I char the whole funnel-shaped wound.

From this operation I have lost but two cases, and I have operated on so many, probably over two hundred, that I have ceased to keep a record of them. At one time we had such a number of cases on hand in the hospital that it was not

easy to find the time to attend to them. One of the cases I lost died from tetanus, and it is the only time I ever had tetanus follow any uterine operation. The second death occurred last year. I had been asked to go about one hundred and fifty miles to perform the operation, but on the day before the appointed one I received a countermanding telegram. It appears that the lady had heard that "clover tea" was a specific for cancer, and wished to try it before resorting to an operation. To this her physicians had to assent, but of course she grew no better. In despair, however, she kept on taking it, until the day before the one on which my summer vacation began. She knew when I was to leave the city, but preferred to put off the operation as long as possible.

So I operated on her, in precisely the same way that I have just removed the diseased cervix, and I did not see her again. The operation was a bloody one, but the case seemed favorable. Unknown to me and to the resident physicians, she had secretly become addicted to opium, and had brought the drug with her concealed in the bottom of a large Saratoga trunk. The night after the operation she was discovered by her nurse to be out of bed, and to be fumbling for something in the bottom of her trunk. This imprudence caused a violent hemorrhage, but it was checked by the resident physician. She did, as she afterwards confessed, the same thing the next night, which caused a fatal hemorrhage. She could have had the opium for the asking, because I make it a rule never to withhold anodynes from the victims of so cruel and so painful a disease as cancer in its advanced stages; but she had made a secret of the habit.

What is the prognosis of our patient? Very bad in so far as a cure is concerned, but very good as regards a cessation of the hemorrhages, a lull from pain, and a reprieve from death. Her appetite will return, and in two weeks from to-day I shall bring her again before you, so that you may judge for yourselves how her complexion will have cleared up, and how improved she will be in every respect. The disease may, indeed, not return in the womb, but it will be pretty sure to invade adjacent structures.

To show you what this operation will do, let me relate a few cases. Three times I have operated, and the disease had not returned in five, six, and seven years after the operation. A few years ago my friend, Dr. W. R. Cruice, asked me to see a very sick woman who lived on the outskirts of the city. Being unadvised as to the nature of the disease, I did not bring my cancer instruments with me. She had a bleeding cancer of the cervix, and had been so greatly reduced by repeated hemorrhages that she looked as if she could live but a few days longer. The cancer was very large, partly excavating and partly vegetating, and the woman so weak that we hardly ventured to operate, and did not dare to give ether. After a hurried consultation, we decided to do our best for her. With my fingers and a sharp uterine curette, which I happened to have in my bag, I removed the cancerous growth. I was without nitric acid, and in its place painted the parts with an ethereal tincture of iodine. Dr. Cruice saw her in the streets some two and a half years afterward, with a market-basket on her arm. Some months later the disease attacked some vital organ, and she died of exhaustion, but without any recurrence of hemorrhage.

Some years ago, Dr. Joshua Evans called me to Branchtown to see a married woman of about forty. I found her bed-ridden and so exsanguined as apparently to be near her end. She was so completely exhausted and stupid that we had to bawl into her ears to rouse her up, as with a patient in the last stages of typhoid fever. The growth was of a vegetating character, very easy to remove, but the woman was too weak to be anæsthetized. Her rest was broken by the severe pains, and her strength wholly gone by repeated hemorrhages. Her complexion had become waxy, and her flesh so translucent-looking as to give the impression that by the aid of a strong light you could map out every viscus in her body. I snared the mass in the wire loop of the ecraseur, and removed it. Paquelin's cautery had not then been invented, so I resorted to nitric acid. An accident now occurred, which I shall never forget. I had an ordinary rubber cork in my bottle of nitric acid. During the jolting of the trip by rail and carriage, the acid attacked the cork and a gas was generated which exploded with violence on my opening the bottle. The contents were forced out as a small spray all over my face, hands, and clothing. I quickly plunged my face and hands into a basin of water, and was fortunate enough to escape with a slight conjunctivitis, which lasted for a few days, and with the loss of a suit of clothes. I now am careful to use a glass stopper, to carry the acid only when I need it, and before opening the bottle to cover the bottle with a wet rag. A rubber cork was used on this occasion because a glass stopper was liable to get loosened and let the acid out over the instruments and other contents of my satchel.

After this operation, and after a constitutional treatment of arsenic, corrosive sublimate, iron, and ergot, the patient improved wonderfully. Her color came back, her pains left, and her hemorrhages stopped. She continued so for nearly a year and a half, coming to my office every month to be assured that everything was right. Each time the womb was found movable, and there was no local recurrence. Later she began to suffer from sacral pains, and I found a hard nodular mass firmly attached to the sacrum. Nothing could be done for her but to allay her sufferings, and she died about two years after the operation.

I could tell you of other instances in which years elapsed without a return of the disease. Yet the disease is so cruel a one, and the prognosis so grave, that it always gives me a pang of pain to discover a cancer.

The operation is now ended, and as there is no hemorrhage, I shall not tampon the vagina. But supposing you operate in the country at a distance from home, and you wish to guard against hemorrhage, or to stop an oozing, what do you do? You take a sponge and pass a string through the centre and tie the two free ends together in a long loop. Do not tie your string around your sponge, for you will then deprive it of its elasticity and the power of expanding. Prepare three sponges in this way, and soak them in vinegar. Pack the first sponge very firmly into the funnel-shaped wound, and make one knot in its string. The

second sponge, with two knots in its string, will be pushed down to the cervix; and the third one, with three knots, will keep the other two in place. In twenty-four hours remove the sponge with three knots, and in forty-eight hours withdraw the sponge with two knots, and immediately afterwards the sponge with one knot. This last one must be removed carefully, and with a rotary motion.

I do not put sponges in my patient's vagina, because she is in a hospital, in which some physician is always on hand. But supposing at 3 o'clock this afternoon the nurse finds our patient bleeding, what instructions shall I give the resident? He will first inject vinegar, and if that does not stop the hemorrhages, he will then pack the womb and vagina with sponges in the way which I have just described.

The second patient, who is now brought in, is in a very bad condition. It was a bad case of advanced disease when she was first operated on, four or five months ago, and I told her husband so at the time. She was so much improved, however, that she has come back to have the operation repeated. On examination, I find the cancer has advanced to the vulva. The vagina is every where implicated, and, as I feared, but little can be done. I shall, however, scrape off some of these bleeding granulations. I dare not use much force, for I am afraid of getting into Douglass' pouch, or into the bladder, as I have on two occasions. I think the curetting will give her some relief from pain and stop her hemorrhages, at least for a time. When you find the disease in the vagina you may be sure that the end is not far off, for the disease will quickly spread by the veins and lymphatics. These patients sometimes die from venous thrombi and consequent embolism. I am sure this patient's sufferings must be very great, and I greatly pity her.

One word in regard to the treatment of cancer cases. Suppose you have operated on a cancer of the womb, and after a time the disease recurs, or perhaps you have not operated because the disease is too far advanced. Now you know that under the most favorable circumstances the woman will not live long, and it is your duty to make her few brief months on earth as comfortable as possible. Therefore, let her have opium enough to give relief, and do not fear that she will become a victim to the habit, for she will not live long enough. One of my patients took thirty-five grains of morphia daily for a week before she died. Without it her sufferings would have been intolerable.

What should the treatment be after an operation? The pain is very trifling. It is, indeed, astonishing that after an operation of such magnitude there should be so little suffering, and it is rare to have a marked rise of temperature. The pain complained of is in the vulva and not in the uterus. We shall give an opium suppository, and begin with the use of quinia at once, to prevent septicæmia. Blood-poisoning is, however, very rare after these operations, because the raw surfaces have been charred and seared with the hot iron, and by the time a purulent discharge begins granulations have formed which do not readily absorb. I expect both of these patients to be sitting up in a week.

While I am washing my hands, let me say a few words as to the danger of contracting disease from these cases. I have a cut on my finger at the present moment. I did not find it out till I made the examination, and acrid discharges got into it; but I do not fear cancer infection as such. If there were any possibility of the kind I would never operate. I might, however, get the wound poisoned by septic matter, not by cancerous matter as such. Once, while enucleating a fibroid of the womb, which had begun to break down, I got a wound that gave me considerable trouble; but my health was below par from a hard winter's work. So dissecting wounds are generally more mischievous at the end of the curriculum than at its beginning. The point, however, which I wish to impress on you is, that you need never fear that you run any risk of being inoculated by cancer germs, but only by the septic matter in those germs.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, April 10, 1884. The President, Dr. Tyson, in the chair.

Rupture of the Heart.

Presented by Dr. T. D. Dunn.

Clinical History.—Wm. D., æt. 58, on the evening of November 3, 1883, invited his daughter to take a walk. While she put on her wraps, he reclined on a sofa. A few minutes afterward his wife heard a faint groan. She immediately went to his side, only in time to witness his last gasp. With the exception of occasional dyspepsia, he had enjoyed good health. He was a man of leisure, full habit, and apparently robust and strong. He had been a constant, though moderate, drinker for some time, but seldom carried it to complete intoxication. He had never complained of any heart trouble.

Autopsy, seventy hours after death. Owing to objections of friends, the brain was not examined. The muscular system was well developed, and there was a large quantity of subcutaneous fat. The lungs and pleura were healthy, with the exception of a few old pleuritic adhesions posteriorly. There was a large deposit of fat in the mediastinum and over the entire surface of the heart. The pericardium contained about one ounce of recently clotted blood. The heart was adherent to the pericardium by two small bands—one near the apex of left ventricle, the other midway between the apex and auriculo-ventricular groove. Externally on the left side of the left ventricle, below the auriculo-ventricular groove, there was a linear rupture about one inch in length. On opening the heart, no valvular disease could be detected, and there was no evidence of atheromatous disease of the large vessels. There was an ulcerated surface about the size of a silver dollar, irregular in outline, and communicating with the external linear opening. This ulceration extended through fully two-thirds of the heart muscle; the muscular tissue of the outer third seemed recently lacerated or separated.

The stomach and liver were normal. The left kidney was somewhat enlarged, the capsule slightly adherent, and cortical substance relatively increased. The right appeared healthy.

Microscopical examination revealed fatty infiltration of the fasciculi, but no degenerative changes of the muscular cells could be detected, nor was there any atheromatous change of the vessels of the heart.

The interesting feature of this case, in connection with those presented to this Society during the past year, is the suddenness of the attack, without any premonitory symptoms, resulting almost instantaneously in fatal syncope.

Diphtheritic Croup.

Presented by W. E. Hughes.

H. G., æt. four years, had been ailing for two days, slightly feverish, and complaining of sore throat, when he began to cough, and his parents noticed slight difficulty with respiration. A day after this, when I first saw him, there was moderate fever, much inspiratory dyspnœa, muffled cough, and whispering voice. The tonsils and pharynx were covered with patches of false membrane, and the cervical lymphatic glands enlarged. On the second day afterward, the dyspnœa became so threatening that I performed tracheotomy. His strength was at this time well preserved. After the operation his breathing became perfectly easy, the temperature fell almost to normal, and his general condition improved markedly. Twenty-four hours afterward, however, the temperature rose, the dyspnœa returned, and he died of apnœa fifty hours after the operation.

Autopsy thirty-six hours after death. Body well nourished. The tracheotomy incision had divided the isthmus of the thyroid gland and the second, third, and fourth tracheal cartilages. The edges of the wound were covered with false membrane. The cavity of the larynx was completely filled by a plug of firm white false membrane, closely adherent to the mucous membrane. In the upper part of the trachea was a thin layer of false membrane; below this the trachea was almost perfectly free, its surface reddened, thickened, and superficially ulcerated. In the right bronchial tube there was an enormous growth of membrane, completely filling the tube, and traceable some distance into its divisions. In the left bronchus was a smaller quantity of membrane not occluding completely its lumini. The left lung was somewhat congested, the right lung contained numerous patches of collapsed tissue, and was in other parts distended with *interlobular* emphysema. This emphysema was most marked at the free edges and surface of the lung, but was pretty generally distributed throughout its substance. There was no distention of the air cells, nor was there any emphysematous condition of the other lung, nor of the tissues of the anterior mediastinum or neck. The cervical lymphatic glands were enlarged and softened. At the bifurcation of the trachea was a mass of calcified glands. Other organs appeared normal.

There were cases of diphtheria in the neighborhood of the patient's residence, so that infection is easily accounted for. A rather curious fact in his family history is that three of his brothers and sisters have died of throat troubles, one of throat complications in scarlatina, another of croup, and a third of spasm of the glottis.

Diphtheritic Bronchitis—Croupous Pneumonia.

Presented by W. E. Hughes.

W. D., white, æt. 43 years, a salesman, was admitted to the University Hospital April 1. Of rather intemperate habits, he had been on a prolonged spree, and much exposed to weather, when three days before, he had been seized with a severe chill, followed by high fever, and, later, intense dyspnœa, with but little cough and no pain. When first seen, he was so weak as to be unable to give a satisfactory history, face and extremities congested, heart feeble and irregular, breathing rapid and labored. The breath was extremely fetid, but he complained of no throat symptoms, and there was no stridor. The cough was hacking, not very troublesome, and he expectorated small quantities of frothy, blood-stained serum. Physical examination showed flatness over the whole right lung, with imperfect bronchial breathing, best marked at the root; over the left lung some impairment of resonance, with large moist rales. He died in less than an hour of apnœa.

Autopsy (notes by Dr. Formad) *Fourteen Hours After Death.*—Pleura of right lung inflamed, plastic exudation, about one pint of serous effusion; left pleura normal. Right lung compressed by the effusion, and uniformly in the beginning of the second stage of croupous pneumonia. Left lung has a spot an inch in diameter in the upper part of the lower lobe, pretty far advanced in the second stage of pneumonia, elsewhere it is simply congested and œdematous. Pharynx acutely inflamed, with some spots of superficial ulceration and scattered deposits of false membrane. Tonsils ulcerated, the bottoms of the ulcers sloughy and covered with offensive false membranes. The same condition obtains in the larynx, its surface is softened, reddened, and dotted with false membrane and superficial ulcerations near the base of the epiglottis is a deep offensive ulceration one-half inch in diameter. Epiglottis œdematous. In the trachea the condition is more marked than in the larynx, about the middle of the trachea the patches of false membrane become continuous, and clothe the whole inner surface of the tubes growing thicker and more consistent as the bronchi are approached and traceable into the finest ramifications of the bronchioles in the larger tubes. tubular in thes mallest solid cylinders. The exudation is but loosely adherent to the mucous membrane, which is red, thickened, or raw. Lymphatic glands of the neck moderately enlarged, red, and softened. Liver, kidneys, and spleen congested, otherwise normal. Heart contains unusually firm white clots.

Carcinoma of Larynx.

Presented by W. E. Hughes.

T. C., æt. forty-nine years, had been complaining of some alteration of voice for six weeks. He was a man of rather dissolute habits, denied syphilitic infection, had never had his larynx injured, nor irritated by foreign substances or gases, and had a perfectly good family history. In addition to the change in his voice, which was at

first the most marked symptom, there was slight tickling cough. Soon after this the glands beneath the angle of the jaw enlarged, and he began to have fits of slight dyspnœa. His flesh and strength failed but slightly, and his appetite remained unimpaired, though a slight trouble with deglutition prevented his eating as much as he would have liked. When first seen, the glands of his neck were enormously enlarged, but painless and still movable. His voice was husky or cracked, sometimes whispering or lost, his breathing difficult and noisy. Alternating with this constant difficulty of breathing were fits of dyspnœa, brought on by no appreciable cause, often so intense as to threaten life. Two days later he died in one of these attacks of dyspnœa, before aid could be rendered. For the foregoing facts I am indebted to the kindness of Dr. George J. Preston.

Autopsy nine hours after death. Body well nourished. Cervical lymphatic glands enormously enlarged, rather firm, no signs of degeneration. Bronchial glands slightly enlarged. In the cavity of the larynx, above the vocal cords, not involving them, but involving the ventricular bands, and extending from them to the top of the larynx, was a firm, pinkish, nodular growth, involving the right side most. The epiglottis was so involved in this growth as to have no vestiges remaining of its original shape. The mucous membrane was intact. The growth had left only a narrow slit for the entrance of air, which could be easily completely closed by pressing down the deformed epiglottis. The pharynx and œsophagus were not involved. The cartilages of the larynx were completely ossified, and around the superior cornu a small abscess had formed, resulting apparently from a necrotic process in the ossified cornu. The trachea and bronchi were normal, the lungs congested. There was a slight increase in the fibrous tissue of the liver and in the substance of the right lobe was a small cheesy nodule. The kidneys were granular, the microscopic examination of the growth was found to be made up of large, irregular cells, separated into masses, in which was no intercellular substance, by a scanty stroma of connective tissue. Scattered through the growth were masses of fibro-cartilage not connected with cartilage of the larynx. The mucous membrane was proliferated, and in places prolonged into the subjacent connective tissue, but nowhere did it take part in the new growth. The epithelium lining the glands was much proliferated, and seemed to have been the starting point of the morbid process. The enlarged lymphatic glands were infiltrated with a growth similar to that in the larynx.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, April 25, 1884. The President, Dr. Henry Beates, jr., in the chair.

Dr. Hannah T. Croasdale reports a case of

Vesico-vaginal Fistula with Inverted Bladder.

The record which is brought to your notice this evening is that of a case which, perhaps, is possessed of more than ordinary interest from two circumstances: first, from the enormous size of the opening in the septum; and secondly, from the fact that from the orifice a bright round body protruded, which was discovered to be the bladder inverted. The patient, M. F., æt. 47, was admitted to the Woman's Hospital, October 11, 1881. She was married at the age of twenty-five, and had one child stillborn. The labor was instrumental, and incontinence of urine occurred soon after it, thirty years ago.

For this trouble and great discomfort the woman never sought relief, and speaks only of her present suffering having begun one year before admission. This suffering had been so intense that she had been obliged to keep her bed for that length of time. The journey from her home had been made on a bed. Her appearance was deplorable. She had constant pain in the lower part of the abdomen; bowels were constipated, appetite poor, face anxious, and she was constantly distressed lest the bed or her clothing be moved, and thereby her sufferings be increased. It seemed almost hopeless to expect to do anything for the poor woman's relief, so disturbed was her health from her desperate condition.

Nausea and vomiting were almost constantly present. Her pulse on the day following that of her admission was 65, temperature 99°, and respiration 26. The quantity of urine in twenty-four hours could not be ascertained. The color was pale yellow; specific gravity, 1002; reaction alkaline, and there was a trace of albumen. After ineffectual attempts, she was finally etherized and thoroughly examined October 29.

The tumor which was so exquisitely sensitive was the inverted bladder, and the exposed mucous membrane was greatly inflamed and bled readily on being touched. The openings into both ureters could be distinctly seen. The mass was grasped, and by gentle taxis was reduced and retained by the slight support afforded by one of Skene's glass stylets, made to pass through the urethra with the distal extremity resting upon the upper edge of the fistulous opening. A vaginal glass plug was introduced into the vagina to aid in supporting the bladder. The inflamed condition of the parts forbade any further procedure at this time.

On the 30th of November she was again etherized and placed in the lithotomy position, and the edge of the fistula, which was about five centimetres in diameter, was carefully pared, beveled from the vesical margin, giving a broad surface on the vaginal septum, and twelve sutures of silver were introduced. It was necessary, before closing the fistula, to liberate adhesive bands at either angle, and then the margins of the opening were closed by the sutures and secured by perforated shot. A self-retaining catheter was introduced to which was attached a piece of rubber tubing for conveying the urine to the urinal. The patient was then placed in a bed and $\frac{1}{6}$ gr. morph. sulph. given hypodermically, and was ordered lime-water and milk every two hours.

The following day, December 2, there was much vesical tenesmus, which gradually subsided, and nothing especially worthy of note occurred until December 7, when the sutures were removed. Union was not perfect at either angle, and in the centre there was a small orifice, which admitted the passage of urine.

January 6, the patient was again etherized; the edges of the three minute openings freshened, and

fine silver wire suture introduced. The central and right openings promptly closed after this second operation, but the left, just at the site of the ureter, admitted the passage of a Snelling's probe.

Then, January 20, February 3, and March 28, I operated, hoping to close this minute orifice which still remained, and which still allowed of the passage of urine when the bladder was filled. Not one of these efforts was followed by any better success. These attempts were always made with a probe carried through the urethra into the opening in the ureter, in order to prevent wounding or closing the latter.

It was now thought best to send the patient home and encourage her coming again in the autumn, as her stay had already been much prolonged beyond the usual time for keeping patients in the hospital, and she was discharged May 8, 1882, quite content on her part with the result of the many operations—six in all. After several months, however, the urine ceased to pass through this opening, probably from the contraction of cicatricial tissue.

I find many contributions to the surgical literature for the relief of vesico-vaginal fistula, but nowhere have I found any record of a case of inverted bladder through the fistulous orifice.

Periscope.

Intermittent Pulse.

The *Med. Press*, July 30, 1884, says:

The phenomenon of intermittency in the pulse-beat is one of such frequent observation that every practitioner is familiar with it, and places on its occurrence a signification which varies within the widest limits. By some it is regarded as a very trivial sign, demanding a merely passing attention; while others, again, attribute to it an importance which it cannot justly claim—the fault usually committed being that of omitting to consider all the circumstances tending to favor its production, and influencing the effects to which it may possibly give rise. The reason why such discrepancies of opinion are noticeable in this connection probably lies in the fact that clinical teachers, during bedside demonstrations, vary much in their descriptions of the phenomenon; for in our own experience we have heard exceedingly inconsistent accounts of what it portends, from different physicians who have been lecturing to students on cases in which an intermittent pulse has been discovered. That this should be so is a misfortune, since any confusion as to principles arising in the minds of those engaged in qualifying themselves for the practice of medicine, only too surely perpetuates itself in their after professional life, leading, it is to be feared, to frequent errors in diagnosis and treatment, which can only be avoided by the possession of accurate and definite knowledge, gained during the pupillary period.

In the presence, therefore, of so great a disagreemeent respecting the meaning of intermittent pulse, useful service is done by the publication of an essay on the subject by Dr. B. W. Richardson, in the current number of the *Asclepiad*, and which is written in a clear, precise, and definite style that will at once commend it to the doubting practitioner. In this paper, Dr. Richardson arrives at the conclusion that intermittency of the pulse is a more common symptom than it formerly was, and that the explanation is to be found in the increased emotional strain and excitement incident to our present mode of living, the affection being due to "nervous exhaustion of the vital nervous system." The detailed causation of the phenomenon, as demonstrated in an exhaustive essay which appeared from his pen in 1868, Dr. Richardson has briefly recapitulated in this later article. He continues: "In itself, when not present in an exaggerated degree, intermittency of the pulse is often less dangerous than it seems. It does not, as might be feared, carry with it the necessary idea of sudden dissolution from heart disease, for, as I have elsewhere shown, the heart is the regulator, not the prime mover, of the circulation. The harmlessness of the symptom in its moderate development is shown by the fact of its common occurrence after middle age, and by the long duration of life in many of those who present it. At the same time the symptom has its significance. Occurring in infancy, it is an important indication of serious nervous derangement. Occurring in young adults, it has the same meaning, and tells the story of commencing failure of power. Occurring suddenly after any great event, which has told upon the mind, it may be a sign of very serious import." By far the greater number of persons whose pulse exhibits intermittency are unaware of the fact, and only in cases where the intermittent period extends over as many as five normal heart-beats, or recurs often in a minute, is consciousness of its occurrence produced, and such cases proceed along a certain course to death when the symptom is persistently present. A most important point, on which Dr. Richardson insists most impressively, and which has a direct practical bearing, is that persons with intermittent pulse offer less resistance to disease, owing to the impairment of nervous energy, of which the pulse-change is characteristic; and also they possess diminished power of recovering from surgical operations, as compared with individuals of normal circulation, and for the same reason, as our author tersely puts it. The phenomenon has its general meaning, both for the physician and the surgeon. It has also its particular meaning, since it may be raised into fatal consequence by disorders which need not, in its absence, prove fatal.

Intermittent pulse in children may pass away, but it is never got rid of when appearing for the first time at or past middle age, although it is not incompatible with the attainment of even extreme old age. One of Dr. Richardson's patients, who died at 86 years of age, was discovered to have this character of pulse when only 42. The symptom may be inherited; a case is quoted of an infant in whom it was distinguished an hour after birth; and now, twenty-five years after, the intermittency always appears under great strain or during depression.

On the subject of treatment in these cases, Dr. Richardson lays down a great number of valuable rules, which will be found of sound value by those who will be at the trouble of studying them. In children especially is it essential to avoid all undue intellectual and emotional strain, and to encourage the taking of a plentiful amount of sleep. In adults, too, equal attention should be paid to removing impressions derived from untoward events, and to regulating diet and promoting repose. The "points of practice" dwelt upon in the paper are indeed exceptionally interesting and suggestive; and taken altogether it is a very valuable contribution on an ill-understood question of medicine.

A Case of Fracture of the Pelvis.

Dr. Edward S. Dwight thus writes in the *Med. Record*, March 22, 1884:

I was called on September 12, 1883, to treat a young German fresco-painter, nineteen years of age, who, while working in a store in this city, had fallen from a scaffolding for a distance of about fifteen feet, the back part of his right hip striking diagonally against a projecting shelf a little above the floor, and the ilium of that side being fractured from a point a little to the outer side of the upper extremity of the sacro-iliac symphysis, downward and outward into the great sacro-sciatic notch.

The patient was unable to stand alone; there was marked crepitation along the line of fracture; efforts to rise caused a sensation of *falling in pieces*, and the thigh could not be flexed to an angle of less than 120° without great pain over the line of injury, and also over the tuberosity of the ischium. Severe pain was also felt in the groin. There was, however, no ecchymosis.

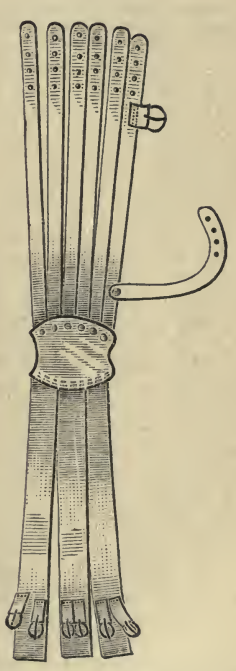
The treatment adopted was as follows: A roller bandage was first applied around the pelvis, and was replaced on the following day by a thick plaster-dressing, enclosing both the pelvis and the upper half of the right thigh. The latter was slightly flexed, the front and outer side of the hip-joint being reinforced by moulded plaster splints. To prevent traction upon the ilium by the dorsal and lateral muscles of the trunk, I also added a few turns of roller bandage, which were carried over the right shoulder and under the perineum. These were tightly drawn, so as to depress the shoulder as much as possible, and were kept from slipping by means of a transverse band sewn to them in front and behind, and passing around the left side of the chest. This contrivance diminished, to a great extent, the throbbings in the injured part, which, together with numbness and tingling along the course of the great sciatic nerve, had been experienced, particularly at night.

At the end of six days, the plaster bandage having become very much loosened by the subsidence of the swelling, it was replaced by another and tighter. This was applied over a layer of wadding and inclosed the pelvis only, the thigh being slung at an angle of 140° by a series of turns of roller which passed around, and were sewn to, the upper rim of this plaster-dressing, and which crossed each other above the thigh, where they were also sewn *together*, as well as to the plaster.

The rim of this second plaster bandage being very thick and firm, prevented upward muscular traction; and the whole apparatus being constantly pulled downward and forward by the weight of the limb, was in consequence kept closely applied against the seat of injury.

Two weeks after the accident, I slung the thigh from the neck also, carrying too a loop of strong cord from the bottom of the sling down below the instep, and allowed the patient to get out of bed and walk into the next room, which, with the aid of a crutch, he was able to do without pain.

Three weeks later this dressing was also removed, and replaced by the following apparatus in leather.



(This represents the back of the apparatus: The central pad rests on the sacrum; the six straps (right side) are all freely movable at their insertion, and are thus susceptible of being placed at any angle, so as to adapt themselves to the outline of the hip; the upper two are applied high up, so as to exert downward pressure upon the crest of the ilium; the next two pass over the great trochanter; and the two lower ones are applied low down, so as to exert upward action upon

the tuberosity of the ischium. The three broad straps upon the left side are firmly sewn to the sacral pad, so as to afford efficient counter-pressure. The strap hanging from the lowest, on the right side, passes under the perineum, and is intended to aid in keeping the whole in place. A broad band of canton flannel was applied around the body before the belt was put on.

The patient was now allowed, after a day or two, to walk about the rooms without a crutch, which he was able to do without pain, the belt acting as a moulded splint, and its lower straps preventing him from unduly raising his thigh. As the belt had a tendency to work upward, another perineal strap, upon the left side, was added with advantage.

Eight weeks after the accident, the patient was able to go out of doors, and could flex his thigh to an angle of 85° without pain. Rheumatic tenderness and twinging pains, at changes of the weather, persisted up to the end of October.

The upper part of the fracture consolidated first. There was no effusion of callus perceptible to the touch, but the iliac border of the sacro-iliac symphysis seems much more prominent upon the injured than upon the opposite side.

A Case of Absence of the Lower End of the Rectum, with Passage of Fæces Through the Penis; Successful Operation for Relief.

Some time since we noted a case like this, which Dr. Wm. Craig reported in the *Edinburgh Medical Journal*. In the same journal for August, 1884, Dr. Francis J. Shepherd writes as follows:

"As Dr. Craig states in his paper that he is not aware of any similar case to his own having occurred, and Mr. Holmes, when speaking of cases where the rectum communicates with the urinary tract, mentions that he knows of no case where the bowel has been reached successfully through a perineal incision, I thought that it might be of interest to place on record a case similar to Dr. Craig's, where operative procedures had resulted favorably. On the 16th of November, 1883, Dr. Molson delivered a woman of a healthy male child after a tedious labor. Next day the mother told him she noticed something strange coming from the child's penis. On examining the parts Dr. Molson immediately recognized the discharge as meconium, and, on further examination, discovered the infant had an imperforate anus. The mother having consented to an operation, Dr. Molson requested me to take charge of the case. The patient was admitted into my wards at the General Hospital on 19th of November, being then three days old, and having since birth passed a large quantity of feculent matter by the penis. The child, which was strong and healthy, had some distension and tenderness of the abdomen, but very slight fulness of the perineum. There was a well-marked median raphé, and a slight puckered depression at the site of the anus. I decided first to try and reach the bowel through the perineum. After placing the child under chloroform, I made a free incision in the median line, dissecting carefully backwards and upwards in the direction of the rectum, and frequently placing my finger in the wound to feel for fulness or fluctuation. I dissected in this way to a depth of fully two inches, when discovering a fluctuating tumor, I punctured it with my knife, and was pleased to see quantities of fæces escaping through the wound. I then enlarged the puncture in the bowel, and without much difficulty drew it down to the external wound, and held it there by cat-gut stitches.

"Almost immediately after the operation the mother removed the child from the hospital, and I did not see it again till 9th of June, 1884. In the meantime Dr. Molson had occasionally visited the case, and instructed the mother, in passing bougies, to keep the anus open. The mother, however, did not attend very scrupulously to directions, and after the operation the opening kept gradually growing smaller. When I saw the child last, it was six months old, and was stout and healthy; the opening had contracted so much that it with difficulty admitted a No. 12 catheter. The mother informed me that the child still occasionally passed fæces by the penis, but only when 'opening medicine' was given. I intend, when I can get the mother's consent, to incise the opening, and I shall insist on her passing her little finger twice daily through the anus, as Dr. Holmes recommends.

"I forgot to mention that the child was the subject of another deformity, viz., absence of the metacarpal bone, and probably the trapezium of the right thumb. It was the mother's fifth confinement; all the other children were born perfect.

"In this case it is highly probable that the rectum opened directly into the membranous portion of the urethra, as, if the connection was with the bladder, it is not probable that the bowel would have been reached by a perineal incision.

"Dr. Craig remarks in his paper that examining the preparation of his case, it is evident that it was possible to pierce the bowel with a trocar, or even a bistoury, but he says, 'to have enlarged the opening sufficiently to have cut down upon the rectum would have been an operation such as few newly-born children could have survived, and even if the child could have survived, the want of development of the rectum would have prevented a successful issue in this case.'

"I cannot agree with Dr. Craig's conclusions, for if the bowel is not reached the child will certainly die, and I do not think fear of the severity of the operation should influence the surgeon in his endeavor to reach the bowel; again, as the rectum is pretty movable in the infant, it can be brought down, as is shown in my case, even if the lower end is undeveloped."

And Dr. D. Duncan Main says, "Two months ago I had a case of imperforate anus. I cut in one and a half inches without finding the bowel. Being afraid to go any further, I dismissed the patient. The following day they came and told me that the child had had an action of the bowels. Of course, I did not believe them, and on making inquiries I found that the child had passed yellow and dark material through the urethra. The child died on the fourth day after operation. I am inclined to think that this was a case similar to Dr. Craig's."

The Physiological Effects of Kairine.

The *Medical News*, August 16, 1884, tells us that M. Morohovetz, of the University of Moscow, has

recently made quite extensive experiments as to the physiological effects of kairine, and publishes (*Medicinsk. Obosrenie*, No. 9, 1884), the following results:

The physiological action of kairine is not simply confined to lowering the temperature. The changes which gr. $\frac{1}{65}$ of kairine will cause in the blood are enormous. In his experiments, Morohovetz used kairine dissolved in a six per cent. solution of common salt, so as to avoid the action of distilled water on the red globules. The blood remained alkaline, but its color changed as soon as a more concentrated solution was used. A continuous current of air deprived of carbonic acid did not restore the red color of the arterial blood. The blood-spectrum was also changed by the concentration of the kairine, and contained four methæmoglobine lines, situated between the C and F lines.

Under the influence of kairine, the blood-globules formed roulettes, at the same time that the middle part protruded from one side to the other. The number of globules does not diminish. The blood of a dog which has taken kairine coagulates almost immediately after it comes out of the vessels. Under the influence of kairine, the red globules of the blood, while preserving their quantitative proportion, undergo a quantitative and qualitative change in regard to the coloring matter; the hæmoglobine is transformed into methæmoglobine, which is precipitated. The change in the color of the blood of a living animal by cyanosis gives a peculiar leaden appearance. The same thing was noticed by Golouboff after the administration of gr. xj of kairine.

The glandular organs are also influenced by kairine. The saliva and bile flow more abundantly after kairine is injected into the blood, or introduced into the duodenum. The bile is viscid and almost black. The pancreas and the kidneys are not influenced by kairine. It is eliminated by the kidneys, as shown by the action of fuming nitric acid on the urine, a bright reddish ring forms between the acid and urine—a ring which is characteristic of kairine in an aqueous solution. When bile is normally excreted, this ring takes the spectrum colors, and the urine gives the greenish color-reaction of biliverdine.

The modifications of respiration and circulation are more rapid and pronounced as the quantity of kairine is increased. The direct injection of it into the blood canses an intense dyspnœa, accompanied by an elevation of arterial pressure in the carotid; this being followed by a diminished pressure, shortening of the pulse-waves, and filiform pulse. After the ingestion of gr. xxv, the heart of the animal was arrested, and it died of cardiac paralysis, the respiration continuing for some time, and being of a Cheyne-Stokes character. At the autopsy, the cavities of the heart were found dilated and filled with blood. The classic experiment on the frog (ligature of a limb), showed that kairine acted similarly to curare on the peripheral ends of the motor nerves.

In experiments on dogs, Morohovetz found no notable abatement of temperature. The experiments of Filehne have shown that, to obtain a notable abatement of temperature, it is necessary to inject kairine continually; less than gr. iv. produces no effect. But it is easy to exceed the required amount, and to throw the patient into such a state that his inspired oxygen is insufficient for his physiological necessities, as kairine deprives the hæmoglobine of a large quantity of its oxygen. Morohovetz terminates his paper by counselling great prudence in the administration of kairine; he considers pulmonary and cardiac affections, and anæmia as absolute contra-indications to the administration of kairine.—*L' Union Méd.*, July 10, 1884.

Hydriodic Acid in the Treatment of Acute Inflammatory Rheumatism.

Dr. James Craig, of Jersey City, N. J., writes as follows to the *Med. Record:*

"Before using the remedy shortly to be spoken of, I was in the habit of prescribing bicarbonate of potassa, which, as a rule, gave relief as soon as the urine was rendered alkaline, which required about a week or ten days, and during that time opiates had to be given to relieve pain and produce sleep. I have also prescribed salicylic acid, but cannot say that I have seen any decided benefit derived from its use.[!] Syrup of hydriodic acid, prepared by Robert W. Gardner, New York, is the remedy *par excellence* for this painful and troublesome affection. I have used it for the past two and a half years in bronchitis and scrofula, but its effects have been most prompt in acute inflammatory rheumatism, relieving pain in from twelve to forty-eight hours. I have been called to see patients suffering from this affection, and found them with high fever, joints swollen, and suffering terribly, and on the following day have been agreeably surprised at their rapid improvement, finding them in a great measure free from pain, and fever reduced. Some other cases take a longer time, but I have yet to find one that was not in a comfortable condition within forty-eight hours. The dose I prescribe for adults is from two to three teaspoonfuls every two or three hours, in a wineglass of water, until relieved; afterward I reduce the dose to one teaspoonful, which may be continued for five or six days, at longer intervals. I was first led to the use of this remedy in prescribing for a patient suffering from bronchitis complicated with rheumatism, its effects being most salutary in the relief of both diseases. I should state that under this mode of treatment the heart has been free from complications—the remedy preventing the exudation and organization of plastic material. I more frequently use it now in rheumatism than in bronchitis—in fact, I use it in all cases of acute rheumatism, and must say have always been pleased with its results. I have also prescribed it in chronic rheumatism, but with less effect. I hope that other physicians will give it a fair trial, and find it as useful in their hands as it has been in mine."

—The *Med. Record* tells us that Professors Virchow and Pettenkofer are busily arguing with each other upon the subject of cholera. The gist of their differences lies in this: Virchow is a contagionist, Pettenkofer is a localist. That is to say, the latter believes that no specific germ can produce cholera unless there is a specific local condition to favor it.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Some further studies of the phenomena of swallowing are given by Dr. S. J. Meltzer in a reprint before us. He takes up for examination the sounds made in the performance of the act, and inquires into their physiological signification. They have positive value as diagnostic signs in a number of diseases.

—— The second annual report of the State Board of Health of South Carolina makes a pamphlet of eighteen pages full of useful suggestions for the public and the authorities, and will, we trust, meet with the attention it certainly deserves.

——The subject of the calcification and decalcification of the teeth is treated of in a paper read before the State Dental Society by Dr. C. N. Peirce. It contains a series of new observations, and is illustrated by diagrams. Reprint from the *Dental Cosmos*.

——The Public Health Laws of Illinois have been issued as a separate pamphlet of fifty pages. It is an excellent summary of what is needed in this direction.

——"Sunshine" is the title of a very handsome illustrated work in large quarto for children, sold for 76 cents, and postage, by Wyckoff, Seamans & Benedict, 715 Chestnut street, Philadelphia. They put it at this reduced figure as a means of recommending the Remington type writer. It is a charming work for the little ones, containing plenty of stories and pictures.

BOOK NOTICES.

Malaria and Malarial Diseases. By George M. Sternberg, M. D., surgeon U. S. A., New York. Wm. Wood & Co., 1884.

This volume, one of Wood's Library of Standard Medical Authors, is a reasonably full monograph of the subject. The author very properly confines the class of malarial diseases to those which are produced by a special poison, their pathognomonic symptom being periodicity. The wider use of the term, to embrace all diseases arising from poisons in the atmosphere, is unjustifiable.

He divides his subject into two parts—malaria and malarial diseases. Under the first heading he discusses the evolution and nature of malaria, its general effects on the system, its antidotes, the means of prophylaxis, and the relation of geographical position. Under malarial diseases he includes only malarial intermittent fever, continued malarial fever, and hemorrhagic malarial fever.

The preparation of the work indicates some haste, the scissors having been used pretty freely (not without due acknowledgement), and the material is not as well digested as it should have been. Still, it is a good book.

Materia Medica and Therapeutics. By J. Mitchell Bruce, M. D., London Sur. 8vo., pp. 545. Philadelphia, H. C. Lea's Son & Co.

This is one of the English series of "Manuals for Medical Students" which are republished in this country by the firm above named. They are the most satisfactory "students' manuals" we have yet seen, and come as near being what they should be—brief, but not superficial; clear, but not trivial—as it is likely such works can be produced.

The present is quite as good as the preceding volumes, and is an excellent resumé of the subject, quite as desirable for the busy physician who would like to refresh his memory as for the student who would post himself for his examination.

The Medical Graduate and His Needs. By Geo. C. Wellner, M. D., Detroit. Geo. S. Davis.

This little volume of 100 12mo. pages gives the young doctor a variety of hints on his outfit, behavior, diagnosis, prognosis, clinical inquiry, hospital practice, etc. We find a good deal in it which is worth reading—a good deal that is trivial also. We will give the author himself a hint. There are other medical schools in the United States than those in New York city, even post-graduate medical schools, with first-rate hospital facilities. It is evident that this will be news to him, so we mention it.

A Compend of Organic and Medical Chemistry, Including Urinary Analysis and the Examination of Water Food. By Henry Leffmann, M. D., etc., Philadelphia. P. Blakiston Son & Co., 1884. Price, $1.00.

This volume is No. 10 of the "Quiz Compends" issued by the publishers. The difficult subject of organic chemistry is treated in a very successful manner by the author; that is, what he tells about it, he does in an unusually lucid manner, and he probably tells enough to carry the student through his examination *cum honore*. Chemistry is generally hated by medical students, and they learn as little of it as they can. This volume will give them that little, at the cost of as small a degree of mental exertion as they can expect.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE ASIATIC CHOLERA—AN INTERPELLATION IN THE GERMAN PARLIAMENT.

After a member of the German Parliament had interpellated the government concerning the possible danger of an invasion of the German empire by the Asiatic cholera, Mr. von Bötticher, Secretary of the Interior, replied to the interpellation June 28th, of this year. The stenographic report, as published by the *Deutsche Med. Zeit.*, No. 55, July 10, is before us; and as the debate which ensued contains some facts of importance and some news, which have not yet appeared in print, we have made in the following a short extract of the minutes for the benefit of our readers.

The secretary first expressed his thanks to the interpellator for having thus given him an opportunity to exert a quieting influence on the whole nation. He then mentioned that the government, immediately on receipt of the news of the outbreak of cholera, at once took steps to obtain authentic information regarding the character of the disease in Toulon, and to consider the measures necessary to prevent an eventual invasion of the empire by the epidemic disease. While the physicians in Toulon had expressed themselves to the effect that the malady raging in Toulon was really the Asiatic cholera, the French government did not seem to be convinced of it, but believed it to be a sporadic complaint, which would probably be of short duration and not spread extensively. This being the present state of affairs, the Minister considered it his duty to watch cautiously the progress of the disease, and meanwhile not to neglect the study of the question, how the epidemic, should it spread, might be prevented from invading Germany, and how, should it enter, its ravages might be limited to the original places of invasion. He then continued, that, thanks to the researches of the German Cholera Commission, and thanks to the results achieved by the same, these questions could be debated far more intelligently, and would produce more certain and reliable measures than had ever previously been possible.

That same morning a commission appointed by the Chancellor had met for the very purpose of

considering these questions, and as such men as Dr. Koch and Dr. von Pettenkofer were members of the commission, the most important results might be expected from its deliberations. While these were not yet concluded, the Minister, who was present at the meeting, could inform Parliament, and through it the German nation, that it had been decided, by no means to draw a cordon around the Empire, for past experience had proven that such a measure had never achieved its purpose, viz., that of preventing the spread of the disease.

At the request of Dr. Koch, in Egypt as well as in India, a cordon had been drawn around the infected districts; but though the measure had been executed as strictly as possible anywhere, it had not met with any fortunate result, the epidemic disease having spread just the same. The Minister, therefore, could assure Parliament that even in case of the spreading of the Asiatic cholera, the common intercourse with a friendly nation, in whose land the disease was ravaging, would by no means be interfered with, and under no circumstances would a cordon be drawn around the Empire.

But there were other measures, attended with far better results, which could be taken and which would surely achieve their purpose. While the Minister was not at liberty to foretell the result of the deliberations of the commission, he might refer to a passage in the report of Dr. Koch, who, probably at present the highest authority on the subject, says:

"I am convinced that, based upon the result which the cholera expedition sent out by the Empire has obtained, measures can be taken which will effectually prevent in future the spreading of the disease in the interior of the country."

"More, gentlemen," concluded the Minister, "we cannot expect. May, by the Lord's will, such measures not become necessary." (Bravo, from all sides of the house.)

Member of Parliament Dr. Virchow then spoke. He drew the attention of the Government to the fact that they had to look first to France for such measures as are needed to prevent the spread of the cholera. "Any civilized nation, in whose country an epidemic disease decimated mankind, owes it to the world to do all in its power to call a halt to the spreading of the contagion. And in this respect nothing is worse than for a government like that of France to imagine that the disease might *not* be the Asiatic cholera, and thus to allow most valuable time to roll by without taking energetic measures. In a case of doubt, it is always better to suppose the worst and to act accordingly; for measures which shall prevent the spread of an epidemic disease never do harm, but have the most salutary influence on the health of the population of any country.

"A transport ship arrives from India, then the seat of the cholera, and anchors in the port of Toulon, where its crew and the transport are put ashore. Shortly after, cases of cholera happen in Toulon, and still to have doubt of their being anything but genuine cholera, is a little strong. In this manner sporadic cases of the disease never happened. And least should such a thought occur in Toulon, which for centuries is notorious as the place of import of all oriental epidemics—a true pest-place. The French Government should have rather at once taken it for granted that they had to do with true Asiatic cholera.

"But there is another place where a stricter quarantine should be observed, a place where alone the importation into Europe of all Asiatic epidemics could be prevented: I mean at the Suez canal. Let me remind you of the English ship 'Crocodile.' On its passage from India to the Suez canal six cases of Asiatic cholera had happened and ended fatally. Notwithstanding this fact, a clear bill of health was given to the 'Crocodile' in Suez. The ship left, and between Suez and Port Said another fatal case occurred on board of her. Still in Port Said again the same certificate of health was granted to her, and she was permitted to proceed to Malta. On this trip nine new cases happened, but nevertheless the ship met with the same criminal negligence, and was allowed to depart for England. That the disease was then not imported into England is one of those fortunate occurrences that seem to protect mankind.

"All civilized governments should unite to force and control such a quarantine at Suez, that such cases as that of the 'Crocodile' can never again occur. Whether the same happened with the French transport ship we cannot tell, as information on this point is still wanting. But we know that the ship came from India, where it had left at the time of a cholera outbreak there; she passed through the canal, was permitted to proceed unmolested, and came to Toulon, where a few days later the first cases of cholera occurred. What I say are facts well authenticated, and the Minister as well as you, gentlemen, may draw your own conclusions from them, and they will tell you what, *ab initio*, the duty of the French Government ought to have been.

"It is no use denying—the sanitary control, as performed by the French Government, is not so strict as civilized nations have a right to demand. I hope to notice soon an improvement, and especially at Suez; otherwise the sanitary measures of other nations are useless.

"It has long been supposed that the Asiatic cholera could not exist so long a time on board a ship. The instance of the 'Crocodile' has now confirmed older cases. Let me mention to you that of the German iron steamer, 'Franklin.' October 10, 1871, it left Stettin, and had, October 14, the last communication with the shore at Christiania. Nevertheless, from November 1 to 13, thirty of the crew died of the cholera. The last case happened November 13, four weeks, therefore, after the 'Franklin' touched land the last time.

"In conclusion, I can only say that I am astonished that our government had not yet sent a commission to Toulon to investigate the disease. The French sent a commission to us to study the trichinæ; they were well received by us; why should we not do the same? Sporadic cases of cholera happen, but the disease since Koch's discovery of the cholera bacillus is now so easily recognized—though without it not less—that there should be no trouble in determining the true character of the epidemic. I myself am against a cordon, as useless."

Virchow ended by declaring that he had the fullest confidence in the wisdom of the government; and then the Minister concluded the debate by insisting that the French Government had taken the strictest measures to prevent the disease from spreading. He mentioned in detail the report of the German Ambassador in Paris, in which it is said that especially disinfection, cleaning, and isolation were strictly attended to, that the troops had been transferred to another city, and that all persons leaving Toulon were under medical control. With reference to the sanitary service in Egypt, the Minister informed the House that the German Government was endeavoring to have all civilized nations act in unison, so as to enforce the strictest quarantine upon all suspicious vessels.

The Minister in closing the debate also made mention of the fact that a German commission would depart for Toulon. We know that such has been done; also, that the French Government has admitted the disease to be genuine Asiatic cholera, and that the latter has spread considerably, though it has not yet found a victim outside France and Italy.

THE PRACTICE OF MEDICINE IN TURKEY.

In 1870 a high Turkish officer, Stephan-Pasha, wishing to reorganize the army medical service in Turkey, induced a number of physicians from Vienna to enter that service. The pay was modest, but large promises were held out for the future. Many young men, attracted by the romance of a voyage in Eastern lands and by the high-sounding promises held out, decided on taking the voyage.

Very few of these medical men who went thither in 1870 are present in the Turkish army: "constant privations at a social and scientific point of view," says M. Fenykövy, "with constant cabals and intrigues, are what we met with."

The foreign physician has under his orders a native druggist and surgeon; the druggist is exceedingly ignorant, barely knowing enough French to read a prescription; those who know how to

prepare pills or Sydenham white decoction are considered models of skill. These native subaltern medical officers are united in their hatred of the physician; they neglect or mal-interpret his orders on all possible occasions, in order to do him the most injury possible.

Formerly there existed at Constantinople a military school of medicine, directed by foreign professors, where the lectures were delivered in French. The results were excellent; each year a number of medical officers, of great intelligence, were graduated, and the most able were despatched to complete their education at Vienna or Paris, their expenses being paid by the government. During the past few years all has been changed, the French language has been replaced by the Turkish, and as there exists no medical literature in that language, a few text-books have been hastily translated.

As a consequence, the young medical men sent to the army at present have very little solid kowledge of their profession. All detest cordially the foreign physicians, through patriotism, and also because their pay is higher and more regularly paid than their own.

It is true that the foreign physician may have recourse to civil practice, but this is very poor in Turkish and Arabian countries.

In Mesopotamia, for instance, the native women during labor are submitted to truly barbarous practices. The torments of a woman in a case of dystocia are unheard-of. Talismans are first applied, then the iman recites from the top of the minaret an ecbolic prayer, and casts an egg to the ground; this is an ancient and respected practice. If it fails, the patient is compelled to walk, the feet naked, over the fragments of a broken vase—the sooner she breaks these, the quicker labor will be completed; besides this process, she drinks water from her father's shoe.

When these mild means do not suffice, and the dystocia persists, recourse is had to more energetic proceedings. The woman is placed on her back, and the omnipresent female neighbor works with her hands and feet on the abdomen. By these diverse violent proceedings a number of persons are killed who would otherwise have been saved by very simple intervention. The most difficult part is to induce a Turk to call a physician. The daughter of a bimbaschi (surgeon-major) had a very difficult primiparous labor. All the national expedients were tried inefficaciously, but when a person present spoke of a European practitioner: "My daughter will die if her time has come," gravely replied the good bimbaschi, "but we will never call a man to her assistance."

SPONTANEOUS PERITONITIS.

The well-known Prof. Leyden has an interesting article in the *D. Med. Wochensch.*, March 24, 1884. After laying great stress upon the fact that peritonitis frequently develops itself in a very similar manner to that of pleurisy, he adduces the proof that spontaneous peritonitis. doubtless belongs to the great class of infectious diseases.

There are many reasons in favor of this view. The sudden beginning with its obscure cause, the high fever and the local seat of the disease in persons otherwise perfectly healthy, the rapid accumulation of offensive pus, and the undisputed epidemic-like spreading of the disease in a locality, all tend to prove its infectious character.

Concerning treatment, Prof. Leyden admits that thus far antiphlogistic procedures, opium, and inunctions with mercurial ointment, are the only means at our disposal and promising any effect. But he throws up the question, why we should not treat such a peritonitis as we do empyema, and suggests the opening of the peritoneal cavity and its washing out with a disinfectant solution. He also mentions a large number of cases where such an operation was performed, and with a favorable result; and though in these cases an encapsuled abscess could be diagnosticated as the starting-point of the malady, he sees no reason why in other cases, where such a condition does not exist, the same good result should not follow the same operation. It is true, it is easier to wash out the pleural than the intricate peritoneal cavity, still, as most grave cases of purulent spontaneous peritonitis end fatally notwithstanding its

local character, it may be well worth while to try the operation, which cannot increase the evil, but only do good. The main point will be to perform the operation as early as possible, as later, when many adhesions have formed, the thorough emptying and cleansing of the cavity would almost become an impossibility.

It is known that this disease is most frequent in children, and as they do not so easily succumb to operations of this kind as adults do, the procedure, so warmly recommended by Leyden, should be tried, and thus the little sufferers be given a chance to survive the infectious malady.

Notes and Comments.

Rectal Feeding and Alimentation.

Dr. Wm. Julius Mickle gives some very useful hints in a paper on this subject published in the *Journal of Mental Science*. In using nutrient enemata he advises that:

Alcohol should not be added to albuminous food.

If necessary, the bowels should previously be cleared out by a simple or aperient clyster, and a daily copious cleansing clyster is required in some instances. The bowels may have to be rested, but we must persevere if the first attempt fails. Where it is apt to return, the patient's best position to receive the enema is on the back or left side. The nozzle or tube should be comfortably warm, so should the food injected. The amount injected may sometimes with advantage be small at first, gradually increasing from 2 to 10 ounces. If the foods are ejected, we may try the plan (Dr. Hine's) of depositing them higher up in the viscus by means of elastic tubing and a funnel. But plugging the anus is often necessary, and has been done in many cases.

Conflicting as are the results of experiments on the subject, he concludes that the rectum and colon digest but little, and that, even when inverse peristole is set up, the action of the bowel upon enemata is chiefly absorptive. If so, the food should either be introduced mixed with digestive substances, or else before administration should in some way or in some measure be digested, and ready for absorption into the venules and lymphatics of the intestinal walls.

The following methods are all considered good:

Leube. Three parts of meat to one part of pancreas, both finely minced and mixed with a sufficient quantity of warm water for clysis. Carefully remove all fat and connective tissue. The hog's pancreas is the favorite.

Rennie. To a basin of good beef-tea, add ½ lb. shredded lean raw beef; ʒj fresh peps. porci; ʒij. dil. hydrochloric acid; warm for four hours; stir frequently. Beaten egg or alcohol (?) may be added.

Catillon. A saturated solution of 19° C. of peptone of meat, 40 grammes; water, 125 grammes; laudanum, 3 to 4 drops; bicarb. of soda, 3 centigrammes.

Dobell. Cooked, finely-grated beef or mutton, 1 lb.; pancreatic emulsion (Lowry & Moore), 1 oz.; pancreatic powder, 20 grs.; pepsine (pig's), 20 grs. Mix quickly, add half an ounce of brandy, and warm water sufficient to bring it to the consistence of treacle.

Henninger. Very lean meat, finely minced, is placed in a glass receiver; water and HCl. are poured on, and pepsine, at the maximum of its activity, is added. The whole is left in a water-bath or stove to digest for 24 hours at 113° F.; it is then decanted into a porcelain capsule, brought to the boiling-point, and while the liquid boils, a sol. of sod. carb. is added to it, until it shows a very slight alkaline reaction. Then the boiling liquid is passed through a fine linen cloth. The liquid is reduced in bulk in a water-bath. White sugar is added before administration.

Mickle. A pint of milk, with one-fifth or one-fourth of a pint of water, is carefully heated to 140° F. Two drachms of liquor pancreaticus (Benger's) and 20 grains of bicarbonate in solution in one or two ounces of water, are added. The whole, in a covered vessel, is kept near the first at 140° F. for an hour or an hour and a half, then thoroughly boiled for two or three minutes. Thus prepared, the food keeps for half a day or a day.

In rectal medication, Dr. Mickle has made extensive use of enemata of chloral hydrate in many cases of epilepsy and of epileptiform seizures. He gives thirty grains dissolved in two ounces of water, and has found it very useful.

The Treatment of Acute Laryngeal Catarrh.

In the course of some practical remarks which we find in the *London Medical Times*, Dr. J. Burney Yeo tells us that in the early stage the advantage of small doses of opium or morphine in allaying irritation and relieving the cough is most marked. It is well to combine them with small doses of ipecacuanha or tartarized antimony. The adminis-

tration of an eighth of a grain of acetate of morphia with one-twelfth of a grain of tartarized antimony every four or five hours; or four or five grains of the compound ipecacuanha powder every five or six hours, will usually relieve most of the distressing symptoms—the tickling cough, the soreness in the larynx itself, the difficulty in swallowing sometimes present, and the hoarseness or impairment of voice. Warm alkaline drinks are also of much value in thinning the tenacious adhesive mucus which often hangs about the glottis and upper part of the larynx, and is difficult of expulsion; for this purpose a third of a tumblerful of Ems, or Bourboule, or Apollinaris water, to which a tablespoonful or two of hot milk or whey may be added, should be drunk every two or three hours.

When it is not easy to get these mineral waters you can prescribe the following mixture, which answers quite as well:

℞.	Sodæ bicarbonatis,	ʒj.
	Sodii chloridi,	gr. xviij.
	Spr. chloroformi,	♏ xxx.
	Aquæ anisi ad.,	℥vj.

M. ft. mist.

Of this mixture two tablespoonfuls should be taken every two or three hours with two tablespoonfuls of hot water or milk.

Counter-irritation and warmth in the shape of a small poultice of mustard and linseed applied over the larynx are of great service. Some, however, prefer cold compresses.

It is of the greatest importance to avoid all causes of further irritation. The patient should therefore be kept to the house, and in one uniform temperature. All exercise of the voice should be forbidden, and the desire to cough should be resisted as much as possible. Violent efforts at coughing irritate and injure the inflamed mucous membrane covering the glottis.

The inhalation of the vapor of hot water or of infusions of demulcent herbs, or warm alkaline sprays, is useful when the cough is hard and dry, and there is difficulty in softening the tenacious and scanty mucous secretions. Direct local applications are rarely advisable in cases of acute catarrhal laryngitis, but they are of great service if the catarrhal condition persists and the case becomes chronic.

Acute laryngeal catarrh is usually a mild and easily managed disease, but it often occurs with troublesome frequency in persons who have to use the voice much in singing or speaking, and it is then more difficult to treat, and tends to become chronic.

Gun-shot Wound of the Stomach: Successful Laparotomy.

From the *Brit. Med. Jour.*, July 12, 1884, we note that Professor Kocher, of Berne, has recently operated with success on a case of gun-shot wound of the stomach. A boy, aged 14, was admitted into hospital half an hour after having received a wound in the region of the stomach, from a pistol-shot aimed at him from a distance of about five paces. He was pale, and complained of abdominal pain; the abdomen was swollen, and distinctly dull on percussion inferiorly. Pressure on the abdomen caused pain. A quarter of an hour later, hiccough, severe epigastric pain, vomiting, pallor, and symptoms of collapse came on. There was tympanitic resonance from the ensiform cartilage to the umbilicus, and complete dullness from the navel downwards and in the flanks; the slightest percussion caused severe pain. Three hours after the injury, laparotomy was performed. On opening the abdominal cavity in the region of the navel, a great quantity of dark blood escaped. The bullet-wound was discovered with comparative ease; it was situated on the anterior surface of the stomach, towards the greater curvature in the direction of the fundus. The wound was circular, with sharp edges, and about half an inch in diameter. The bullet could not be found, nor was there any aperture of exit. The edges of the wound were united, first with two catgut ligatures, like an ordinary wound, and then a continuous silk suture was applied, for the distance of about an inch, so as to invert the serous coat around the wound. Recovery was retarded by an abscess which formed in the track of the sutures in the abdominal wound. Professor Kocher declares that, considering the impossibility of recovery in cases of gun-shot wound of the stomach when active measures are not taken, it is the duty of the surgeon to perform laparotomy whenever an injury of that kind is suspected. The case is recorded in a recent number of the *Korrespondenzblatt für Schweizer Aerzte*, where Professor Kocher publishes several other recent cases of operations on the stomach. Out of three cases of resection of the pylorus, one recovered; a case of gastro-enterostomy, for cancer of the stomach, terminated fatally; one case recovered where the stomach of an agricultural laborer was opened for removal of the end of a corn-catcher, which had broken of during an attempt to extract a large tin nail which the patient had swallowed. The nail itself could not be found. Professor Kocher has also recently performed three gastrostomies for the relief of can-

cerous stricture of the œsophagus. One of the patients died within twelve hours, from collapse; the second died on the third day with septic symptoms. The third recovered, left the hospital, and died suddenly two months after his discharge, apparently from an apoplectic stroke.

The Treatment of Ozæna.

The *Centralbl. für die Gesam. Therapie.* of February, 1884, contains an article on the treatment of ozæna, by Dr. Roth, of Vienna. He objects to the general use of the term as applied alike to all conditions which may cause the particular symptom, and he would use the name ozæna only for what he calls the genuine variety, characterized, not by any decay of the bones or soft parts, but by hyperæmia and hypertrophy of the mucous membrane, with increased quantity and diminished fluidity of the secretion, which rapidly dries, and hardens into cakes. The mucous membrane is often found in parts in a state of atrophy, which seems to be the secondary condition of the foregoing hypertrophy; and this atrophy may extend to the turbinated bones, which will then present no trace of their previous form or structure. The fœtor results from the access of germs to the secretion, as has been proved by experiment. When the anterior and posterior nares have both been stopped, so that no air has been permitted to enter, the fœtor has failed to appear, but has been detected after the secretion has been exposed to the air for some time, when micrococci and bacteria have been found in it in great numbers. The proper name for such an affection is rhinitis chronica atrophicans fœtida, and the indications of treatment are to loosen and remove the secretion, to restore the mucous membrane to its normal condition, to remove the odor, and to cure any prevailing dyscrasia. Dr. Roth effects those ends by means of plugs of cotton-wool, charged with iodoform, which he introduces into the nostrils at night, and removes in the morning. They act as a disinfectant, retain the secretion, and exercise salutary pressure on the mucous membrane, irritating it slightly, so that an increased quantity of blood is brought to it, and the secretion becomes more fluid. After the removal of the plug, the nasal cavities are washed out with a solution of thymol, carbolic acid, or chlorate of potash, combined with alum or tannin, by means of a special nasal spray, which conveys the fluid to the very back of the nose. Special causes must be removed according to their indications, but in the case of tuberculous affections the local treatment should be confined to disinfection, and reliance is to be placed chiefly on general dietetic measures. Dr. Roth concludes by remarking that only those cases which come under treatment in the early stages of hypertrophy are curable, but that, unfortunately, this, obstinate and peculiarly objectionable complaint is generally first seen when atrophy has already begun, and when the treatment of the fœtor is all that can be hoped for, until the mucous membrane, with its glands, is completely destroyed.

Crossing the Legs, and the Mode of Sitting.

In the *Brit. Med. Jour.*, May 10, 1884, we read that M. Delaunay, of Paris, has made an extended and careful investigation to ascertain if, in the majority of cases, the right upper and lower extremity be crossed over the left, or the left over the right, and which side most persons incline to when in the sitting posture. According to M. Delaunay, certain breeds of dogs such as terriers, Newfoundlands, and poodles, cross the right paw over the left. The Chinese and Japanese cross the left arm over the right. Europeans cross the right over the left. M. Delaunay observed, in the *crèches* and *salles d'asiles*, that infants under three years of age cross the left arm over the right, older children crossing the right over the left; sixty per cent. doing so at six years of age. Robust children cross the right arm over the left; the idiotic and weak, including those who are incapable of working, cross the left over the right. The Calmucks and Arabs cross the right over the left, like the Europeans. A great many women cross the left leg over the right. Among the opera-dancers some always cross the right leg over the left, but not one the left over the right habitually; the majority cross the left over the right or the right over the left indifferently. Robust children cross the right leg over the left earlier than their weaker playmates. Persons who cross the right leg over the left lean towards the left when sitting; those who place the left uppermost lean to the right. Hence, consistently with what might have been expected from what is observed in children with regard to crossing legs, until six years of age children lean towards the right, and afterwards towards the left. French schoolmasters, it would appear, try to prevent their pupils from assuming this position, believing that scoliosis results; hence they encourage or enforce the use of elbow-rests (*accoudoirs*), which oblige the children to sit straight—a useless measure according to M. Delaunay, as the position they choose is in conformity with the process of evolution. Tailors affirm that the back

of a pair of trousers is always more worn on the left side than on the right. Left-handed people always sit towards the right. M. Delaunay concludes from these observations that the left brain develops previously to the right, and finally the right predominates.

Sexual Insanity.

In the *Brit. Med. Jour.*, June 28, 1884, Dr. Macleod published a brief paper on this subject. This disease generally occurred in young girls and women from 18 to 24, who were affected with amenorrhœa or dysmenorrhœa. An illustrative case was that of a girl, aged 24, who came of a healthy family, but was not so strong as the others. She was well until 17; menstruation was painful and irregular. Her habits then changed; she became dull, gloomy, and at times irritable. This went on for years. Then she became excitable, and was removed to an asylum for nine months. She did not improve. She then became depressed, and her health fell off. Two months ago, she came to Beverley. She was dull and apathetic, and would not work. She was untidy and dirty in her habits; at times she showed erotic tendencies. She was free from organic disease. Her menstruation was normal; she was somewhat anæmic. These patients manifested erotic tendencies, and frequently masturbated. The character was perverse. The disease was sometimes attributed to disappointment in love, but probably existed before the supposed disappointment. There was often hereditary predisposition, and neurotic tendencies. The disease was characterized by sharp attacks of excitement, followed by apathy. It manifested periodicity. The physical health was generally poor, with anæmia and a general want of development. The prognosis was favorable if the patient lost the characteristics of girlishness and developed into womanhood. In the treatment, the two chief points were the establishment of the menstrual flow, and the restoration of the bodily health. Fat-forming foods, with iron and tonics, were best. Sedatives and stimulants should be avoided. Asylum treatment was the best, where there was a regular system of work.

Resorcin.

Recent investigations have demonstrated that the disagreeable side-effects of resorcin, the nausea and vomiting, are by no means due to the remedy itself, but to the impurities accompanying it. Since the *resorcinum purissimum vel resublimatum* has been in the German market the reports of reliable authors have accumulated, which prove that resorcin, if pure, is the most reliable remedy for vomiting we probably possess, and not only in adults, but also in children. Besides its prompt effect in this regard, it is said also to stimulate and to strengthen to an extraordinary degree the digestive functions of the stomach and of the upper part of the small intestines.

Dr. Justus Andeer, in Munchen (*Allg. Med. Centr. Zeit.*, July 5, 1884), recommends resorcin in these cases, in doses varying from sixteen to forty-eight grains, and draws the attention of the profession to the effect which the remedy exerts in very large doses, such as employed in anæmia and chlorosis. Symptoms of intoxication set in, and the individual under its influence acts like a drunken person. A good *old* red wine (Bordeaux, Macon, etc.,) acts like a specific; a few glasses of it putting at once an end to the symptoms mentioned. This action of the red wine is probably due to its containing iron in considerable quantities.

Salivary Incrustations on Dental Plates.

Dr. James Craig, of Jersey City, N. J., thus writes in the *Dental Cosmos:*

The methods usually resorted to in removing salivary deposits from dental plates are mechanical, viz., by scraping, consuming considerable time, and friction with a wheel brush. The method I have adopted is simple, and may be considered a chemical one. The saliva, having an alkaline reaction, its salts being principally sodium, calcium, and potassium phosphates, forms a deposit that may be removed by using a solution of carbolic acid from 3 to 5 per cent., the strength depending upon the thickness of the incrustation. The carbolic acid being antiseptic and non-corrosive in the strength mentioned does not injure the plate, but keeps it sweet. Theoretically, the carbolic acid, combining with the alkaline bases, forms carbolates, thereby loosening the deposits. By immersing the plate an retiring at night, and allowing it to remain in the solution until the following morning, the incrustation is easily removed by a flow of water from the faucet and gentle friction with a tooth-brush.

Primary Cancer of Bladder.

This condition is not common, yet Dr. Whitney showed a specimen of primary cancer of the bladder, situated in the right posterior wall, and involving the opening of the right ureter, to a recent meeting of the Suffolk District (Mass.) Medi-

cal Society. The right ureter was dilated, as well as the pelvis of the kidney, which was in a condition of hydronephrosis. The left ureter was normal in size, and the kidney showed fatty degeneration of the convoluted tubes. The lumbar glands on the right side were diseased, and the liver was filled with nodules of new growth.

The microscopic examination showed the disease to be of the flat-celled variety of cancer.

The specimen came from an old man who had had hæmaturia for eight months, but no pain. Gradual loss of strength and death.

It is well to bear this case in mind as it may serve to explain some cases of persistent and intractable hæmaturia.

Prickly Heat.

Dr. Henry T. Wharton tells a most distressing case of this affection in the *Lancet*, August 2, 1884, wherein a man of exceptionally good health, who knows nothing of indigestion or biliousness, suffered from most intolerable prickly heat. The eruption appeared most profusely on his back and arms, and the itching was intense. It was finally suggested after all other remedies had failed, that perhaps the short-sleeved light undershirts that he wore in summer might be responsible for the trouble, owing to their inability to absorb the perspiration or to protect the skin from sudden chills. He commenced to wear throughout the summer the thickest long-sleeved shirts, made entirely of wool, such as he wore in the depth of winter. The result was the absolute cessation of the prickly heat.

Correspondence.

Sewer Ventilation.

Eds. Med. and Surg. Reporter:—

Great cities, indispensable to the business facilities of nations, must at the same time be admitted to be "great sores on the body politic." Their contaminated atmosphere is the enduring source of many dangerous and fatal diseases from which the residents of the open country are exempt. The most fertile origin of some of our most fatal diseases is the gas generated in sewers, caused less by the gas *per se* than by the myriads of microscopic animalculæ and fungi, with their germs and spores, of which this gas is the proper home. By our present imperfect system of sewage pipes, this prolific cause of diphtheria, typhoid fever, and other malignant diseases, is conveyed into every house provided with the *convenience* of drainage pipes; and no system of traps or disinfectants as yet devised has to any perceptible extent served to abate the evil. An adequate amount of disinfectants, however great their individual virtue, would be unattainable, to say nothing of probable negligence in their use.

The proposed plan of the London Sewer Board to solve the question of ventilation of sewers by causing a ventilating passage to be built in the chimney stack of each *new house* when being built, and running the shaft well above the roof of the house, although suggestive of good results, would be at best partial and uncertain in its operation. As a general and more certain method, I would suggest the plan of running a sufficient number of metal pipes from the main sewers into the stacks of furnaces now existing, or to be built for the purpose in the most elevated portions of the city. Whilst the liquid contents of sewers gravitate to the lowest points, the buoyancy of the enclosed gas causes it to ascend to the highest. The draught of a furnace would greatly increase the rapidity of its ascent. Once within the furnace, the gas, with all its power for evil, would be instantly and permanently destroyed.

If there are not now in Philadelphia a competent number of furnaces, others could be erected by the city authorities, the expenses of which might be compensated by leasing to manufacturers and artisans the power thus to be acquired.

I cannot doubt that this plan, if skilfully carried out, in connection with improved pavements and proper facilities for street cleaning, independent of jobbing, would prove of incalculable advantage as regards the question of healthfulness.

I offer these suggestions in the hope that some influential and philanthropical citizens possessing a better knowledge of the practicable working out of the idea, may take it in hand and subject it to a fair and impartial test.

Jno. T. Huddleson. M. D.

Glen Mills, Del. Co., Aug. 29, 1884.

Prevention of Conception.

Eds. Med. and Surg. Reporter:—

I notice in the Reporter of August 16th, a note from Dr. Matteson charging Drs. Goodell and Waugh with "cant and humbug," and that the general practitioner "who, from false delicacy, neglects to instruct his gentle patients how to protect themselves without physical injury, and also without sacrificing anything of modesty or morality," is worthy of reproach. As I have understood it, the position of those teachers is, that the methods of preventing conception known to them are, without exception, productive of physical injury, and therefore not to be recommended by the physician. We are thus led to infer that Dr. Matteson either is aware of some method of preventing conception, which is harmless physically, consistent with "modesty and morality," and of which these teachers are ignorant, or that he has evidence to show that some of the methods they condemn are harmless, modest, and moral. In either case it would seem incumbent upon him to show precisely wherein the "humbug" lies, to state explicitly the method which he is in the habit of recommending, and to produce the clinical evidences upon which he bases his judgment. This, rather than a wholesale charge of "cant" and "false delicacy" would seem likely to prove a real contribution to the solution of a vexed question.

L. B. Tuckerman, M. D.

Cleveland, O., Aug. 19, 1884.

Borate of Quinine.

EDS. MED. AND SURG. REPORTER :—

Your notes on borate of quinine have made a decided impression on me for several reasons, but one of which I will trouble you about. In this latitude we sometimes have congestive chills, pernicious intermittent, etc., in which condition the administration of quinine is—per orem—simply out of our power. To use a solution hypodermically, the acid necessary in making a solution often causes abscesses, sores, etc. Therefore, if the borate is so readily soluble, it is *the* thing we need, and I hope you will induce some of your city manufacturers to prepare it, or some of the wholesale dealers order some from Europe. And let the readers of the MEDICAL AND SURGICAL REPORTER know of it. S. W. CANTWELL, M. D.

Trenton, Tenn.

NEWS AND MISCELLANY.

The Perkins Tractor.

In the course of an article on "Medical Delusions," in the *Boston Med. and Surg. Jour.*, August 14, 1884, Dr. Albert Day gives the following account of the Perkins tractor:

It is not a century since the Perkins delusion with its metallic tractors turned the heads of many wise and good people. Dr. Elisha Perkins, of Plainfield, Connecticut, invented his tractors, and began practice with them, about the year 1796. One part is composed of steel, and the other seems to be of brass or some metallic compound. The operation consisted in uniting the large ends and then drawing the sharp points over the diseased parts, no incision being made. This being done several times completed the operation.

Dr. Day then publishes a lot of letters which Dr. Perkins received from prominent persons endorsing his tractors, and goes on to say that about the time of the popular excitement occasioned by the wonderful cures by the "tractors," Dr. Benjamin Douglas Perkins, son of Elisha, went to England, the wonderful cures by the magnetic tractors having preceded him. He settled in Leicester Square, London, where he proposed to make good the fame of his father. He then took out a patent for the wonderful "tractors." The most wonderful stories soon obtained general circulation, and the press groaned with pamphlets all vaunting the curative effects of the metallic tractors, which were sold at five guineas the pair. Perkins gained money rapidly; gouty subjects forgot their pains in the presence of this new remedy; the rheumatism fled at its approach, and toothache, which is often cured by the mere sight of a dentist, vanished before Perkins and his marvelous steel-plates.

The benevolent Society of Friends, of whose body he was a member, warmly patronized the invention. Desirous that the poor, who could not afford to pay Perkins five guineas, or even five shillings, for his tractors, should also share in the benefits of that sublime discovery, they subscribed a large sum and built a hospital, called the "Perkinean Institution," in which all comers might be magnetized free of cost. In the course of a few months they were in general use, and their lucky inventor in possession of five thousand pounds.

Dr. Haygarth, an eminent physician of Bath, recollecting the influence of imagination in the cure of disease, hit upon an expedient to try the real value of the "tractors." Perkins' cures were too well established to be doubted, and Dr. Haygarth, without gainsaying them, quietly, but in the face of numerous witnesses, exposed the delusion under which the people labored with respect to the curative medium. He suggested to Dr. Falconer that they should make wooden tractors, paint them to resemble the steel ones, and see if the very same effects would not be produced. Five patients were chosen from the hospital in Bath upon whom to operate; four of them suffered severely from chronic rheumatism in the knee, ankle, wrist, and hip, and the fifth had been afflicted for several months with gout. On the day appointed for the experiments, Dr. Haygarth and his friends assembled at the hospital and with much solemnity brought forth the fictitious tractors; four out of five patients said their pains were immediately relieved, and three of them said they were not only relieved, but very much benefited; one felt his knee warmer, and said he could walk across the room; he tried and succeeded, although on a previous day he had not been able to stir; the gouty man felt his pains diminish rapidly, and was quite easy for nine hours, until he went to bed, when the twitching began again. On the following day the real tractors were applied to all the patients, when they described their symptoms in nearly the same terms. The same experiment was tried in other hospitals with the same results.

An account of these matters was published by Dr. Haygarth in a small volume entitled, "Of the Imagination, as a Cause and Cure of Disorders, exemplified by Fictitious Tractors."

The friends of Perkins were unwilling to confess they had been deceived. They found at last that no one believed in them. The Perkinean Institution fell into neglect; and Perkins made his exit from England, carrying with him about fifty thousand dollars.

Anti-Vaccination Experience.

The following is the experience of a man who refused to have his child vaccinated as narrated in an English legal journal:

"It was an action brought against the governor of Portsmouth jail and two of his wardens for improperly treating the plaintiff while an inmate of the jail. The plaintiff, a commercial traveler, was ordered by a magistrate for the county of Sussex to cause his daughter, Charlotte Mabel Kennard, aged three, to be vaccinated. This he refused to do 'on principle,' as he said. He was consequently summoned before the magistrate and fined. He refused to pay this fine. A distress was accordingly levied on his goods, but was returned unexecuted. The magistrates accordingly ordered the plaintiff to be imprisoned, but without hard labor, for fourteen days in the Portsmouth prison, in default of the payment of the fine. The plaintiff was accordingly arrested and conveyed to Portsmouth jail. There he was or-

dered to take a bath, and whilst he was in the bath his ordinary clothes were taken from him and prison-clothes substituted, which he was compelled to wear. His deceased wife's wedding-ring, which he always wore, was removed from his finger. He was also throughout the fortnight compelled to pick oakum, to sleep on a plank bed, and to take his exercise with the ordinary prisoners. He was also not allowed to procure his own food, although he offered to pay for it, but was compelled to live on the prison fare. Counsel contended that he was not a criminal, subject to prison discipline. Lord Justice Lindley gave judgment for the defendants. This seems *prima facie* a hard case, but if men choose to break the laws, they must not expect any lenity because they act 'on principle.'"

Dental Caries in Normandy.

From a foreign exchange we learn that several departments in Normandy furnish a considerable number of rejections among the recruits drawn for military service. The Seine Inférieure for example, furnishes a mean of 50 per cent. of rejected conscripts. This singular fact in so wealthy a department, in which the population seems strong and prosperous, has excited the attention of Dr. Chervin. He finds that the most frequent malady giving rise to rejection, after cases of "general weakness," which preponderate, is dental caries, which, taking the department altogether, furnishes 15 per cent. If the different cantons in the department are examined, a great difference among them is discovered, varying from 80 per 1,000 the lowest, to 229 the highest number. Pursuing his investigation of the department for twenty years, M. Chervin arrives at the conclusion that race is the chief cause of the predominance of caries. Examining one of the ethnic elements which is the most persistent, and which furnishes most information on the subject of race-stature, he finds that the department is inhabited by two different races, the shorter in the east, and the taller in the west. In the population of the higher stature, dental caries is far more frequent than in that of the lower stature; and this fact is not peculiar to the Seine Inférieure, but is observed also in other departments.

The Placenta of Birds.

The *British Med. Jour.*, August 9, 1884, says:

"Birds have hitherto been considered to be implacentary; but some recent researches by M. Duval, communicated to the Society of Biology of Paris, seem to show that their ova possess a rudimentary form of that characteristic organ of the mammalia. In the course of his investigations, M. Duval has made a number of complete sections of the eggs of small birds, at various stages of incubation, and has found them to be divisible into three layers or levels: 1, that of the large end, which contains the embryo; 2, that of the middle, with the allantois; 3, that of the smaller end, which is occupied by a pouch-like prolongation of the allantois containing albumen. From the wall of this pouch a number of villosities project into its interior. These persist during incubation, and disappear on its completion, the albumen being by that time absorbed. The outside of the pouch is applied to the inner surface of the egg-shell. This villous bag M. Duval takes to be the rudiment of a placenta, and considers that its inner surface is concerned in the nutrition, its outer with the respiratory function, of the embryo."

The Doctor without a Coat.

In the *Med. Record* we read that Prince Bismarck's physician, Dr. Schweininger, who was some time ago made a professor, has now, it is said, been given an order of nobility and made Professor in the Faculty of the Berlin University, with authority to deliver certain courses at Charité. *Apropos* of Dr. Schweininger, the German papers publish in the humorous column the following story: "A servant in Münich was showing the sights to a country visitor. The latter wanted to know all about the figures and statues on the University building. Rather than confess ignorance, his city friend gave the names of distinguished contemporaries to the various gods and goddesses, and other immortals in stone. 'And that figure,' he said finally, pointing to a very classically-dressed statue on the façade of the left wing, 'is Dr. Schweininger.' 'Aha!' said the admiring visitor, 'but where then is his coat?' 'Oh,' replied his friend, 'since he cured Prince Bismarck, the people have sent for him from all over the country, and he has had to travel so hard that he has worn off his clothes!'"

The Virus of Hydrophobia.

The *N. Y. Med. Jour.*, August 23, 1884, published the following letter received by Dr. A. S. Heath, of New York city, in reply to a letter to Pasteur:

"August 8th.

"*Sir:* In the absence of M. Pasteur, who is in Copenhagen, I reply to the letter which you addressed to him.

"In an animal that has died of hydrophobia there is nothing virulent except in the saliva, the salivary glands, and the nervous system. The blood, the muscles, and the viscera, do not appear to contain the virus of rabies. I do not know of an instance of inoculation of rabies by the performance of an autopsy.

"The attenuated virus that you ask for is still under investigation. Thus far, it has been tried only on dogs, and in the present state of our knowledge, M. Pasteur would not dare to make one of it on man.

"Accept, sir, the assurance of my highest consideration. Dr. Roux,

"Adjunct Director of M. Pasteur's Laboratory."

Does a Man Own His Head?

One of the questions which an Englishman recently left his heirs to quarrel over, was the right to his head. The deceased had sold it to the local physician in consideration of his paying the funeral expenses, and when the time came for the delivery to be made, he called for it; but the heirs, who said they were perfectly willing to pay the funeral expenses themselves, demurred, and refused to carry out the agreement. The aid of

the courts was then invoked, and at last accounts the matter was not decided. In the meantime, the value of the head for purposes of dissection, if that is what the physician wanted it for, is rapidly diminishing, and soon will be of no value whatever. The English courts have at various times held that there could be no property, in the ordinary sense in which the term is used, in a dead body; and the interesting question now comes up whether the ownership, such as it is, is vested in the person himself or in his representatives.

Victoria and Tasmania as Resorts for Consumptives and Persons Afflicted with Lung Disease.

Dr. J. W. Barrett concludes an article on this subject in the *London Med. Times*, by thus summarizing:

1. That they should, if possible, go out by the fastest and best equipped steamers.
2. That they should go to Melbourne and at once travel north of the dividing range to such places as Sandhurst, or anywhere in the valleys of the Goulburn or Murray.
3. That they should obtain out-door employment on a sheep or cattle station, or some similar place.
4. That, should the summer try them, and the practice of midday rest fail to relieve, they should go to Tasmania for January and February.

That, however, in all cases, they must remember that their place of safety lies north of the great dividing range.

Incomes of English Physicians.

From *Gaillard's Medical Journal*, we learn that of English doctors, Radcliffe made over $35,000 a year in the height of his fame; Mead, $25,000; Baillie, $45,000; Sir H. Halford, $55,000; and Sir B. Brodie $85,000 in the year but one before his retirement, the largest income known. Radcliffe once received $8,000 as special fee for visiting Lord Albemarle at Namur; Granville $5,000 and his traveling expenses for a visit to St. Petersburg; and recently Sir W. Gull $5,000 each for two visits to Pau, and $7,500 for traveling to Perthshire and remaining a week with a patient. But the fee of fees was that received by Dr. Dinesdale in 1768, for inoculating the Empress Catherine and her son at St. Petersburg, viz., $60,000 paid down, a pension of $2,500 for life, and the dignity of a baron.

Items.

—Lawson Tait says: Any woman who has an ovarian tumor removed in her own house is a fool for her pains.

—The Roumanian Government has sent Dr. Maccovich as a "commission" to Marseilles, in order to study the cholera.

—Somnambulism is one of the subjects to be taken up by the committee for the collective investigation of disease in England.

—The British Medical Association created a new section at its recent meeting at Belfast—that of Pharmacology and Therapeutics.

—Clear boiling water will remove tea stains; pour the water through the stain, and thus prevent its spreading over the fabric.

—In the *Brit. Med. Jour.*, June, 28, 1884, Mr. H. A. Latimer reports a case of retained menses from imperforate hymen; epilepsy; operation; recovery, with temporary relief from epilepsy.

—In the Cincinnati *Medical News*, June, 1884, Dr. George W. Vogeler reports two cases of intestinal obstruction; one from impacted fæces; the other by stricture due to cancer.

—Professor R. Harvey, of Calcutta, advocates the use of the forceps in breech presentations in certain cases (*Indian Medical Gazette*, June, 1884). A number of obstetrical authorities have now declared in favor of this innovation.

—A remedy for rhus poisoning is proposed by Mr. Wiegand, in the *Am. Jour. Pharm.*, July. It consists in the application, without friction, of cloths moistened with fluid extract of senega. Two or three applications are said to effect a cure.

—Before undertaking a *post-mortem* examination, Dr. Clevenger recommends holding the hands over strong aqua ammonia, when the smarting will reveal all the sensitive or abraded places that need a touch of the caustic before beginning the examination.

—In a case of death from the eating of raw ham, which occurred recently at Arietta, in Hamilton county, N. Y., and which has been investigated by a committee of the State Board of Health, the muscular tissue of the patient has been found to be swarming with trichinæ.

—"Doctor, I want to thank you for your great patent medicine." "It helped you, did it?" asked the doctor, very much pleased. "It helped me wonderfully." "How many bottles did you find it necessary to take?" "Oh, I didn't take any of it. My uncle took one bottle, and I am his sole heir."

OBITUARY NOTICES.

ROBERT E. ROGERS, M. D.

Dr. Robert Empie Rogers, late Professor of Chemistry in the Jefferson Medical College, of this city, died suddenly on September 6. He was born in Baltimore, Md., in 1814. After a thorough preliminary education he graduated in medicine from the University of Pennsylvania in 1836. From 1844 to 1852 he was Professor of Chemistry in the University of Virginia. He assisted his brother, J. B. Rogers, in preparing his edition of "Turner's Chemistry," and, on his death, succeeded him as Professor of Chemistry in the University of Pennsylvania. Dr. Rogers was a son of the late Dr. P. K. Rogers, of this city, and a brother of James Blyth Rogers, late Professor of Chemistry in the Washington Medical College at Baltimore, and then in the Medical College at Cincinnati. Another brother was Henry Darwin Rogers, the geologist and Fellow of the Royal Society, who died in Glasgow.

In 1877 he resigned his chair in the University to accept a similar position in the Jefferson Medical College, which he held until a few weeks since. Mrs. Rogers died a few years ago. Dr. Rogers leaves no children.

INTERNAL HEMORRHOIDS—THEIR TREATMENT—A PLEA FOR CARBOLIC ACID.*

BY T. J. HAPPEL, M. D., TRENTON, TENN.

The pathology of hemorrhoids is too well understood to need any comment—their causation is a matter with which every surgeon is familiar. I purpose confining myself to their treatment only.

Gross, in his last edition, says: "For the radical cure of internal piles, the proper operation is ligation," etc. This position is taken by Erichsen, Druitt, Allingham, and in fact also by all of the older writers upon the subject.

This mode of operating is superior to that of the knife or scissors, which should never be resorted to in the treatment of internal hemorrhoids; but to my mind it has always been an unscientific, not to say an unsurgical procedure, to ligate a tumor and return the same within the rectum, and there leave the gangrenous mass, suppurating and slowly sloughing off—the patient suffering all the while this process goes on (from five to ten days) more or less pain; sometimes so intense as "to resist large doses of opium," and then frequently a slow convalescence, often complicated by the existence of long-continued and painful ulceration at the seat of one or more of the ligatures, and then sometimes death from pyæmia, tetanus, constitutional disturbances, or from the drain from the ulcers above referred to. Fatal cases from this operation have been reported by many surgeons, among whom are Cooper, Brodie, Lee, Lane, and others. Mr. Lane reports four cases of death from tetanus alone. Prof. Ashurst reports two from the same cause. Mr. Henry Smith reports several fatal cases as having occurred in his own practice and in that of personal friends.

The most favorable exhibit for the operation by ligation is that made by Mr. Allingham; but a close reader after Mr. A. will inevitably come to the conclusion that many of his cases of operations, when slow in recovering, were sent from the hospital to the country, and when they did not return for further treatment were considered cured; but such a conclusion can hardly be considered correct, inasmuch as many of those cases perhaps concluded, as is the habit of persons afflicted with any chronic disease, that nothing could be done for them, and remained away in despair, or have gone to some other surgeon.

The danger of septic poisoning in such an operation, if there were no other danger, seems to me to be sufficient to deter any one from it, if any other operation is possible. We know that the rectum does absorb medicines when injected into it, and if medicines, why is there not always more or less danger of the absorption of the putrid material thrown off during the five or ten days occupied by the hemorrhoids in sloughing off, to say nothing of the fine opportunity afforded for this absorption when the slough separates, leaving a healthy surface ready to absorb anything.

One more objection to the operation is the liability to a return of the disease, perhaps not at the site of the hemorrhoid removed, but adjacent to it. I have in my mind cases in which such results followed within two years.

* Read before the Tri-county Medical Society of West Tennessee, June 10, 1884.

The operation by "clamp and cautery," originally practiced by Mr. Cusack, of Dublin, and then by Mr. Henry Lee, of London, and then much more extensively by Mr. Henry Smith, of the same city, is certainly a great improvement, at least upon theoretical grounds, upon the method by ligation. You remove with the knife or scissors, after clamping the tumor, that portion which, in the method by ligation, is returned within the rectum and left to slough off. You thus remove at least one element of danger of death from pyæmia or septicæmia.

The question might be asked, "Does not the eschar left after the application of the actual cautery give rise to the same danger that the method by ligation does?" Not to near the same degree, nor for half as long a time. As the bulk returned in the method by ligation is greater, to that extent is suppuration greater; and whilst the time occupied in the sloughing process, after an operation by ligation varies, as claimed by its strongest advocates, from five days as the shortest to ten as the longest, the separation of the eschar left by the second method requires only from three to five days.

Whilst the operation by clamp and cautery is a little more lengthy and tedious, the pain attendant upon it is no greater than in that by ligation, and in many cases less; especially is the pain less in the first five days after the operation.

In the operation by ligation the patient is confined to his bed, as a rule, for at least a week, whilst in the operation by clamp and cautery the confinement to bed does not usually extend beyond the third day, and at the end of a week the patient is, as a rule, walking about. In this operation we have the same ulcerated surfaces to heal that are met with in the operation with the ligature, and hence an objection to the operation.

I have performed the operation with success in several cases, and was often annoyed by the complaints of the patients about the long-continued discharge of mucus, muco-pus and blood from the rectum.

One troublesome symptom common to both these methods of operative procedure as a sequence of the operations, and very often present, is retention of urine.

Of the two operations, it seems to me that there can or ought to be no hesitancy in choosing the latter, were nothing better offered.

The operation by nitric acid is almost universally condemned, except in the case of sessile tumors, which are small or moderate in size, of a bright red aspect, resembling a small strawberry, composed of arteries, not veins. The most satisfactory, as to results, of all the operations performed for the radical cure of internal hemorrhoids is that by the use of carbolic acid injections.

Mr. Allingham opposes the method, from having tried "the injection plan on some few cases, but the result was much pain, more inflammation than was desirable, a lengthy treatment, and the result doubtful." He bases most of his objections to the plan of treatment upon a pamphlet read before the Kentucky State Medical Society in 1878, by Dr. Matthews, of Louisville, Ky., in which Dr. M. endeavors to show that the injection of the pile is painful, and that death is to be feared from peritonitis, embolism, or pyæmia. The operation at that time was in its infancy, and was no doubt done very unskilfully. No one now would think of injecting as much as ten or twenty drops of the solution of carbolic acid and glycerine. No wonder the pain was excessive and the inflammation greater than was desirable.

Dr. Gross, in the last edition of his great work, sets forth very plainly the *modus operandi* with carbolic acid, fixing the amount to be injected at from three to six drops. The smaller the quantity the better, and very rarely will it be found necessary to use more than that, except in very large tumors. The process of the cure is generally that of shriveling up or mummification, occasionally sloughing. The larger the quantity of the acid, as a rule, the greater the amount of inflammatory action likely to be set up, and the greater the probability of the tumor sloughing out. The weak solutions of the acid are objectionable on account of the bulk necessary to be used. Where only two, three, or four drops of the acid are slowly injected through as small a needle as possible, the less in degree and rapidity is the inflammation, and the surer is the tumor to shrivel and gradually disappear. The mummifying process is attended with virtually no danger of pyæmia—and it is extremely doubtful whether there has ever been a case of embolism from the operation. The action of the carbolic acid (two parts of the acid, to one of glycerine or olive oil) injected in small quantities into these tumors, seems to be altogether different, so far as producing coagulation is concerned, from that of any other agent heretofore used. Other agents produce this coagulation (clotting) of the blood contained in the veins or arteries of the tumor almost instantaneously, whilst the circulation through them is active, and hence the danger of embolism, and the almost certainty of sloughing. The

carbolic acid, when injected in small quantities, appears to act directly upon the coats of the blood-vessels, ramifying through them, gradually inflaming, and thickening them, thus producing a gradual narrowing of their calibres, decreasing in this way slowly, yet surely, the supply of blood and finally cutting it off altogether, so that the pile mummifies instead of sloughing. Where the larger quantities of the acid are injected the whole process is carried on so rapidly that the vessels are, so to express it, at once ligated or sealed up, and the tumor sloughs. In those cases operated on by myself I have never had one to slough—they have always shriveled. In the largest tumors I have never injected more than five drops of the carbolic acid and glycerine mixture of Dr. Gross. The fact that the tumor *sometimes* sloughs cannot be used as an argument against the operation as this sloughing process always is met with in the operation by ligation. No progress is there made toward a cure by that method of operating until the ligated portion of the tumor sloughs. If, then, in every case treated by carbolic acid injections, every tumor sloughed the patient would be in no worse condition than he would have been in had the tumors been ligated. The fact of suppuration and sloughing would weigh then equally against both, and would make an argument in favor of the clamp and cautery, where the tumor is entirely removed and nothing is left to slough except the cauterized line of tissue. But the facts in the treatment of hemorrhoids (internal) by hypodermic injections of carbolic acid are that not more than ten per cent. of the cases properly treated even slough. The rule is that they are cured by shriveling up, due to the gradual cutting off of the supply of blood sent to them.

In 1878, I operated by this method upon my first patient. The case was one of twenty years' standing. He was unwilling to submit to the ligature, and agreed that I might inject. I chose the two largest tumors, carefully coated them over with cosmoline, and then applied it pretty thoroughly to the other tumor and the rest of the protruded and everted rectum. The tumors were nearly as large, each of them, as small hen eggs, always protruded when the bowels acted, and had to be replaced by manipulations long continued. Frequently the patient lost as much as a pint of blood at one sitting.

I injected four drops of carbolic acid and glycerine solution into each tumor. The patient complained of a pain resembling that produced by a bee sting, and continuing for five minutes. After that, there was no pain of any consequence, and each day grew less. On the day after the treatment the patient went to some light work, and lost no time at all after that day. The tumors gradually decreased in size, mummifying slowly. The third tumor, not injected, underwent atrophy. At the end of a month the patient reported himself almost well, and at expiration of the second month as entirely cured, becoming relieved at the same time of a troublesome dyspepsia. This same patient has been under observation from that time till now, and never has been troubled at all since.

My second case was operated on in August, 1880. The history of it is almost identical with the first one as to duration, etc. The patient was utterly unfitted for anything, and would never consent to any operation as long as he could replace the tumors, which were always forced out beyond the sphincter of the rectum with each action. Finally, on one occasion having failed himself to replace them, and his family physician not succeeding any better, he sent for me to operate on him, expecting me to use the clamp and cautery. Remembering the favorable result of the first case, I decided to inject. There were two large tumors and one small one. I injected the large ones each with four drops of the acid and glycerine, and then with difficulty replaced the protruded and swollen mass. The injection of the first tumor gave almost no pain, but the needle being full of the acid when the point came in contact with the surface of the second hemorrhoid, the acid spread over a small space and caused him to complain for a few minutes. After replacing, I then administered morph. sul. grs. $\frac{1}{3}$ hypodermically, and left him with directions to keep in bed three days and take a dose of morphiæ sul. gr. $\frac{1}{4}$ every four hours if needed to produce freedom from pain.

On the third day he was to move the bowels. I saw nothing more of him until I met him in town three weeks afterward, when he reported himself well. He said that he had suffered no pain, except when his bowels moved the first time; that he was able then to do more work than he had done in years. This patient I see frequently, and up to this date—nearly four years—he has had no trouble. Since those two cases I have operated frequently, with the same uniform good result.

No tumor has ever sloughed out under my treatment. I attribute that result to the fact that I inject a very small quantity of the acid. I have operated on patients at my office, and have known them to get well without losing a half day even

from work. In May, 1883, I injected a case of thirty years' standing. The tumor would, as the patient expressed it, drop out when he was simply walking about, and always protruded if he attempted to lift or carry any heavy weight.

The treatment and progress was the same as in the other cases. The patient now reports that he is entirely well, and that the only evidence of ever having had any trouble with the rectum is that one part of it feels rather gristly. This condition is no doubt due to the non-absorption of all the plastic matter thrown out into the cellular tissue between the mucous and muscular coats of the rectum.

In none of the cases that I have operated on have I ever had any excessive inflammation, or, as already said, any sloughing. The pain has always been slight at the time of the operation—similar to that produced by the sting of a bee, as expressed by most of the patients; and this pain has been followed by a sense of relief, due to the anæsthetic effects of the carbolic acid.

I cannot see how peritonitis can be caused by the treatment, as suggested by Allingham and others, unless the acid were injected into the cellular tissue of the pelvis by thrusting the needle through the pile, and then through the muscular and peritoneal coats of the rectum; but such an operation would be inexcusable. The needle must only be carried to the base of the tumor. Any one with any skill at all can easily measure on the needle the proper depth to carry it—then and then only should the acid be ejected, and drop by drop then. The needle having been retained in the tumor for a minute is then withdrawn. I cannot see where the danger from embolism or pyæmia can be nearly so great as in the other methods of operating. Granting, however, that there is danger from embolism, there is fully as much danger from the same source in all surgical operations. If the large injections are used, we have a condition of things similar to that produced by ligation of the tumor; for the blood vessels are closed almost instantly, and under such circumstances the one operation offers no danger not presented by the other. When the small injections are used, ♏iij. to ♏iv., the process cannot possiby involve any danger of embolism. The progress of the case toward recovery is that is of mummifying or shriveling, or, perhaps, more properly, atrophy begins.

So far as pyæmia is concerned, what has already been written will show how little danger belongs, in my opinion, to the operation by injecting carbolic acid, as compared with that by ligature, or that by clamp and cautery. One danger belonging to the operation by ligation, admitted and frequently referred to by Mr. Allingham, and a number of cases reported in which it occurred with almost fatal results, is that of secondary hemorrhage. The operation by carbolic acid injection is entirely free from this danger when injected in small quantities, so as to produce shriveling, not sloughing.

So far as after-treatment is concerned in cases operated on by injecting carbolic acid, you will need nothing except to cause the bowels to move every day, or every second day at least, unless the patient is debilitated, when it will be necessary to administer suitable tonics.

This matter of after-treatment presents one of the great arguments in favor of the carbolic acid injection. In all of the other operations the after-treatment is generally a matter of great importance. An ulcerated surface is left to heal and cicatrize. It often becomes necessary to stimulate the process of cure by astringent and other injections, or to dilate the rectum with a speculum, and make caustic or other applications directly to them. Nothing of this kind is necessary after the use of the acid, unless too much has been injected and the tumor has sloughed. This, however, is the exception, not the rule.

Another objection which can be urged against all the other methods of operating upon hemorrhoids, referred to in this paper, is the possibility of a stricture of the rectum, following and resulting from the healing and cicatrizing of the ulcer, always in those operations produced, with the contraction of the rectum therefrom resulting.

There can be no possible danger of such a result after the method by injection, except in the few cases of sloughing of the tumor from the too free use of the acid.

UTERINE AND OVARIAN REFLEXES.

BY A. E. CALKINS, M. D.,

Of Bath, Clinton county, Mich.

Nothing so perplexes the ordinary physician as making a correct diagnosis between inflammatory diseases of the organs of generation and idiopathic disturbances of the stomach, heart, brain, and lungs. Very frequently indeed are we called to prescribe for a patient with all the symptoms apparently of gastritis, valvular disease of the heart, meningitis, or phthisis, for which we give the appropriate remedies indicated from every possible standpoint, and authorized by every imaginable theory of etiology, with no results what-

ever, excepting perhaps to further irritate the patient and befuddle ourselves; until at last, perhaps a more careful examination of the minutiæ and an appreciation of the more trivial symptoms, with a greater or less admixture of miraculous chance, we are led to remedy some abnormal condition of the sexual organs, when an almost instantaneous happy result follows.

Dr. Fothergill thus writes of these cases: "All sorts of combinations of drugs are tried, and fail to procure any alleviation of the condition. The medical attendant is nearly worried out of his life, consultants are called in without avail, the friends of the patient are worked up to a state of feverish anxiety, the sufferings of the patient are not inconsiderable, and so the case wears on for weeks. Here the absence of local indications throws the medical man off the scent as to the real nature of the malady with which he is brought in contact, and the ovaries are unsuspected. All the remedies are futile and inoperative, because not directed to the origin of the trouble. The case lingers on till it would seem the general mal-nutrition starves down the congested ovary into quietude, and then the reflex disturbances cease."

To make the difficulty in diagnosis still more formidable, there is an entire absence of local pathological changes in a majority of these cases, while in the remainder similar pathological conditions produce varied and often antagonistic phenomena; and again, there exists no relative proportion between the gravity of the lesion and the effects following it; in one case the reflex disturbances far surpassing what would be expected, and in another falling far short of it. Of course we must admit some existing irritation, either special or general, even if the most conscientious investigation fails to disclose it, for undoubtedly these exceptional cases will be satisfactorily explained when future researches in pathology more accurately determine what constitutes morbid anatomy and pathology.

The anatomy of the nerve supply of the body and neck of the uterus and ovaries has been, and still is, the subject of much controversy. All are agreed, however, in giving to the sympathetic system the much larger control of their functions; and especially are the fibrils of this system numerous in the fundus and body of the uterus and ovaries. As the hypogastric has filaments from the sacral nerves, it is exceedingly probable anatomically, and clinically certain, that the cervix is controlled to some extent by the cerebro-spinal system; its nerves passing directly through the hypogastric plexus to the cervix. The effects of uterine and ovarian excitation are very similar, and are explained anatomically by the connection of the two organs by their nerve supply from the sympathetic; the ovarian and hypogastric plexus freely anastomosing with each other between the folds of the broad ligament. In this manner a direct and continuous chain of communication exists from the hypogastric plexus to the ovarian, and through this with the upper aortic and renal, and so with the solar plexus. This makes the communication close between the organs of generation and the stomach, heart, kidneys, and lungs, through the sympathetic system; and through the cerebro-spinal nerves with the brain.

The nervous supply of the sexual organs in the female fully explains their physiological action, and to a great degree the results occurring when from any cause they are excessively or morbidly irritated. Physiology teaches us that stimulation of the sympathetic system excites contraction in the coats of the arteries and capillaries, and therefore inhibits the secretion of the gastric juice and other digestive fluids. Thus we can easily understand why and how nervous currents set in motion by pelvic irritation, contract the gastric blood vessels, for example, and arrest the flow of the fluids necessary for digestion, and hence arise all those symptoms of indigestion described by writers under the head of "Ovarian and Uterine Dyspepsias," such as acid stomach regurgitation and fermentation of food, flatulency, diarrhœa or constipation, with pain, nausea, and vomiting.

The causes producing uterine and ovarian reflexes may be studied as exciting and predisposing. Under exciting causes may be mentioned all malpositions of the uterus and ovaries, traumatisms, hyperæmias, and inflammations, however produced. These exciting causes would of course produce their appropriate reflexes even in a healthy organism, but when the general system is reduced and otherwise weakened by some one of the predisposing circumstances, their manifestations are made more emphatic and decided. A constitutional "dyscrasia," or "susceptibility," or "neurasthenia," inherited from parent to child, the same as occurs in other diseases, would be the most evident predisposing condition; while a particular acquired condition of mal-nutrition, both local and general, is perhaps the most constant factor, as well as the one that would be the most readily influenced by the proper treatment. That such a localized condition, resulting from changed

nutrition, is a cause of no small moment in the production of pelvic reflexes, may be perceived at a glance, as past cases are reviewed in the memory. Nothing is more common than an abnormal supply of blood to the pelvic organs. It may be decreased in quantity, resulting in atrophy, superinvolution, and the menopause; but more commonly it is increased, or the return flow retarded, as is the case in all flexions, versions, and prolapses. So, also, is the nutrition materially disturbed, and hence the reflex centres more intensely irritated, by any mechanical conditions, whether from local congestions pressing upon nerves, or old cicatrices imprisoning nerve filaments. or adhesions resulting from past inflammations, or any conditions changing the normal blood and nerve supply, and position and mobility of the pelvic viscera.

General mal-nutrition is likewise a cause of considerable magnitude in the production and continuance of uterine and ovarian reflexes. The want of general "tone" of integrity, resulting most frequently from a non-assimilation of food, produces a susceptibility to all kinds of nervous irritations. Neuralgias, myalgias, and hysterias are but the cry of weakened nerves for more nourishment. *Debility*, either general or special, is an universal condition of the sympathetic nervous system in all cases of pelvic reflexes. A small number of patients may have an externally healthy appearance, as indicated by a ruddy complexion and a fair amount of muscular development; yet in them it cannot be admitted that these appearances exclude the possibility of debility either structural or functional, of the sympathetic centres and nerves. Debility is also the chief cause of neuralgias, and we have, as might be expected, similar and even identical symptoms resulting from reflex disturbances. We have the intercostal pains, with the three tender spots of Villeix, one under the left mamma, the second at the base of the left scapula, the third at the exit of the posterior rootlet of the sixth or seventh intercostal nerve from the spinal column, and palpitation.

It may be claimed by some that hyperæmias and inflammations must necessarily furnish an increased amount of pabulum to the neighboring nerves; but it must be remembered that in such congestions the nerve filaments are pressed upon by the increased bulk of the tissues, without in any manner being protected, as they are during the hypertrophy of gestation by an increased protective envelope. In fact, I think that it would be very hard to show any condition resulting in uterine reflexes that would not show either a lessened number of nerve filaments from destructive lacerations, or a crippled condition of those remaining. Another proof that debility of nerve structure and centre is a paramount circumstance in all nervous reflexes, is the good results obtained from a tonic and supporting treatment, and the opposite effect in depressing and weakening management.

The landmarks by which we are to judge of uterine and ovarian irritation are many and somewhat novel, yet all have a definite significance. As their remote manifestations are all transmitted through the sympathetic nerves and reflected by the sympathetic ganglia, it is in the organs supplied by this system that uterine and ovarian reflexes will appear, and the character and function of such organ will determine the form and character of the reflexes as symptoms. But it must be remembered that the severity of the reflex manifestation bears no sort of relation to the location or intensity of its cause in the sexual organs.

(*To be continued.*)

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER, M. D.

Reported by W. H. Seelye, A. M., M. D.

Varioloid.

This patient was admitted December 17. He is 20 years of age, single, was born in the United States, and is a waiter by occupation. Gives no family history bearing upon the present difficulty. Has never had syphilis, and does not use alcoholic liquors. Has never had rheumatism or malarial fever. Patient was perfectly well until last Thursday night, when he had a chill, followed by a slight fever and headache, and pains in the back, limbs, and face. On Friday the chill was repeated, and he felt sick and became weak. He did not have any cough or sore throat, but he did have a slight nasal catarrh. Has no vomiting, and his bowels are regular and micturition normal. On admission his pulse was 108, respiration 28, and temperature 102.6°. His urine was free from albumen.

Gentlemen, this is the history of an acute disease in a young man who was perfectly well until last Thursday, when he was seized with a chill, which was followed by pain in the head, back, and a considerable degree of fever besides. He came in on Saturday, and I saw him for the first time last evening, and then he had a temperature of nearly 104°. I examined him then for an eruption, and I found one. I saw some erythematous spots which looked a little suspicious, and also some follicular spots, which looked like an acne, on the breast. It was too early for a typhus

eruption to appear, and although we get an eruption in variola on the second or third day, yet I did not then think that this was a case either of variola or varioloid. But from the appearance of the eruption to-day, and the fact that I now find a well-formed vesicle upon his soft palate, I conclude that it is one of the variolus diseases.

But you might ask me how I would distinguish a variola from a varioloid by the eruption. The variola eruption appears on the third day, but it is quite copious and it appears all at once, and all of the spots present one characteristic form and appearance; while the varioloid eruption comes out in a sparse and irregular way, a few spots appearing one day and a few more the next, and so on for several days—so that by the fourth day you have spots representing the several successive stages of the varioloid eruption; thus some will be erythematous merely, and some will be papules, pustules, and vesicles, some of which will be umbilicated and others not. You see then the importance of the eruption in all cases of essential fevers which begin, as this did, with no local organic disturbance, in enabling you to decide which one you have to deal with. And this is not always easy to determine in the first stage of the eruption. But the period at which the eruption appears will aid you, for it varies much in the different fevers. Thus, in scarlet fever it appears on the second day or earlier, in variola on the third day, in measles on the fourth, in typhus on the fourth or fifth, and in typhoid on the seventh. The eruption here is not very numerous, but some new spots have appeared since I last saw him, upon the abdomen, chest, and face, and some have already reached the vesicular stage. There are also a few on the legs and upon the back. Here then we have the eruption in its erythematous and vesicular stages, but it has not yet arrived at the pustular stage. I find in the roof of his mouth upon the soft palate a vesicle which is perfectly characteristic, and which therefore provides a point which would enable you to diagnosticate a case of this kind at once. So far as I know there is not any such vesicle to be found in the mouth in typhus or typhoid fever, and in scarlet fever and measles there is only an erythematous condition of the mucous membrane. But in variola and varioloid a vesicle is formed of the same nature as those upon the integument.

Now, as to the course of this malady, after seven or eight days there is a subsidence of the fever, and a resolution of the tegumentary lesion then begins to take place, and is completed in the course of three or four weeks. This is a mild case which we have here, though there is a pretty high temperature; but this sometimes occurs in varioloid. He at one time had a temperature of 104.3° and 104.5°, but it has diminished some to-day. You will sometimes meet with this degree of fever in varioloid, and there may even be delirium, and neuralgic affections of great severity. So, though I suspected at first that this was a case of variola, I now believe it to be varioloid.

Rheumatism.

The next patient was admitted December 12. He is a man 20 years of age, single, a native of Scotland, and an iron-moulder by trade. Has never had syphilis or gonorrhœa, nor any rheumatism before this attack. There is no family history of rheumatism. He is a beer drinker, but does not use liquor to excess. Last summer, while he was working in an iron foundry at Cold Springs on the Hudson, he had an attack of malarial fever. He has been very well since then. But three weeks ago he was out one night, and exposed himself and caught cold, which settled in his left knee and right wrist, which became swollen and painful. The pain in the joints continued, and it finally became so severe that he applied here for relief. He did not complain of any præcordial pain, and his bowels and micturition were regular. On admission his pulse was 70, respiration 18, and temperature 100°. There was no albumen in the urine.

You observe, gentlemen, that this is not the history of a very acute attack of rheumatic fever. He has been a healthy man, and he traces this attack to exposure to cold. And I have told you before, that exposure to cold and wet is not an infrequent cause of arthritic inflammation. Some authors recognize the possibility of a catarrhal inflammation of the joints, just the same as of the mucous membranes, as a result of exposure to cold. Whatever the truth as to this fact, it is certain that we often see rheumatism originating, as in this man, after more than usual exposure and fatigue which causes a more or less severe inflammation of the joints. But I think that in such cases the rheumatism is of a very much less acute variety than in those cases which depend upon a diathetic condition of the blood, which has become deteriorated by indulgence in fermented liquors. This man kept about for several days after his attack began, and he received no benefit from the treatment which he had. But when he came in here, and a blister was put upon the joints, and salicylic acid was administered internally, the salicylic acid and the blister, one or both, relieved his pain. But there was not the subsidence of the fever also which we usually get from salicylic acid, which appears to be an antipyretic of very great value in this disease. As it did not act as such here, however, while it seemed to produce some disturbance of digestion it was withdrawn, and salicylate of cinchonidia was substituted for it. This combination is sometimes more easily borne by the stomach, and it is highly spoken of as a substitute for salicylic acid. But there still continued to be some fever until this morning, when it fell to the normal.

Now, a word about the use of blisters in the treatment of inflammatory rheumatism We do not very often resort to them in acute cases of inflammatory rheumatism where there is a high temperature and great tenderness and swelling of the joints. And, in my experience, they are not nearly so valuable here as in cases of subacute rheumatism. But where they are used in the very acute cases, it is almost invariably in connection with some other anti-rheumatic treatment, so that we do not get, I think, a true estimate of their value. But in those subacute cases where there is a moderate amount of effusion into the synovial cavities and some thickening of the tissues around the joints, I believe that rest of the part, and the local application of a blister, are very valuable—while in cases of acute inflammation of the joints I do not believe that

blood-letting and counter-irritation are of much value.

There is one remark I wish to make about the salicylic acid treatment of rheumatism. I have told you before that of all the remedies which have been suggested for the cure of rheumatism, and their name is legion, none have given such satisfactory results or proven so valuable as salicylic acid. Now the history of the treatment of rheumatism constitutes a very remarkable chapter in the history of therapeutics. There is no disease for which a greater diversity of remedies has been proposed. At one time acids were in favor, and at another alkalies; at one time purgation was practiced, and at another opium was used; and salts of every variety have at different times been supposed to have some superiority in the treatment of this disease. As a result, skeptics have arisen who doubt the efficacy of any treatment at all in rheumatism. So about fifteen years ago, at the time of the introduction of Fuller's alkaline treatment, Drs. Gull and Sutton treated a number of cases with simple mint-water, and their results were as good as were obtained with the alkalies. They believed that all cases ran a regular course, and all had a tendency to end in a week or nine days, or in a fortnight, or else in the classical period of six weeks. But when you come to the salicylic acid treatment, there is no question as to its power. When you see, as we frequently do here, the greatest relief produced within twenty-four hours by the administration of ten-grain doses every two hours, and you find at the same time a great improvement in the appearance of the joints, I think that we get here not only a "post hoc" but a "propter hoc" argument to justify us in attributing the improvement to the use of salicylic acid.

Pneumonia.

Patient is 50 years of age, and a widow. Was born in Ireland, and is employed as a domestic. Was admitted December 17. Has been accustomed to have occasional attacks of rheumatism, and three years ago had malarial fever. Six days before she came to the hospital, she caught cold while scrubbing the floor, and the next day, Tuesday, she had a chill and complained of malaise, nausea, headache, pain in the right side, and fever. There was no disturbance of micturition, and the bowels were regular. At the time of her admission, she was suffering from headache, and she complained of pain in the lower portion of the right chest, and also in the upper part under the axilla, which was increased by pressure and upon taking deep inspirations. Her pulse was 120, respiration 28, and temperature 103.4°. Her urine contained a little albumen, but no casts, and it was dark colored, and had an acid reaction, and the specific gravity was about normal.

This patient, gentlemen, entered on the sixth day of the disease, and she has been here two days. Her temperature when she came in was 103.4°, and the next day it rose so high as 105.4°, and since then it has ranged from 103.4° to 104°; but this afternoon there is a falling temperature. This morning it was 103.7°, but at noon it had declined to 102°, where it remains now. There is also a falling pulse and respiration, so you are now seeing this patient in the period of defervescence; and as this is the eighth or ninth day of her disease, she will probably by to-morrow evening have a temperature of 99° or 100°, or possibly it will be normal. This, therefore, is a typical case of pneumonia.

Now, in making the physical examination, it is not always a good plan to move a patient with pneumonia, and to make him sit up. You should not be too curious about getting all the physical signs, for you may be doing harm by disturbing the patient, and the vital signs which you can take without disturbing him constitute a very fair guide as to his condition. It now and then happens that syncope takes place unexpectedly when a patient with pneumonia is suddenly brought into the erect position, and so many cases terminate. In examining this patient now, I do not know as I shall be able to make out the same condition of affairs as was found when she came in—that is, a pneumonia affecting the upper and lower portion of the right lung, with an area of healthy lung tissue between. It is possible that this area has been absorbed and included in the inflammatory process, and so I shall now find evidences of consolidation over the whole lung posteriorly. However, we will see.

Upon percussion and auscultation, I find that the lung is still in the same condition as I have just described.

Now, gentlemen, you observe that the safety limits in the vital signs have been exceeded in this patient, for she had at one time a temperature as high as 105.4°, but she has not had a pulse exceeding 120, nor have the respirations been greater than 36. These variations in the vital signs are sometimes of very great importance. For example, a rising temperature may accompany a fall in the pulse-rate, and this is not a good combination. And here there was a very high temperature at one time, but a pulse that was not excessively rapid, namely, 120; but I would not consider that a very grave combination. If, however, there had been a very high temperature and respiration, and a very slow pulse, that would have been a bad combination; and so, also, would a slow respiration and a high temperature and rapid pulse. There is no combination so good as one which shows a sort of harmony in the vital signs, and to have them all rising together is better than any irregularity among them. If you have a harmony, though it may be a harmony at a very high pitch, yet it is better than a condition of discord. With a temperature of 104° and a pulse of 120, and respirations 40, you have a harmonious condition of things, and you may consider that the patient is all right. But with a temperature of 105° and a pulse of 60 or 70 and respirations 50, you have a very discordant condition, and there is little reason to hope for a favorable result.

I will make no extended remarks upon the treatment of this case, for it is the same as is carried out in most cases of pneumonia. The indications are simply to control the fever and support the heart. The fever is controlled by quinine and alcohol, and the heart's vigor is sustained by digitalis and stimulants. In many cases little or no treatment is required but rest, proper feeding, and watching. The patient has been taking

moderate doses of quinine, alcohol, and digitalis. The indications for the use of these I have already described to you.

Medical Societies.

LOUISVILLE MEDICAL SOCIETY.

Reported by Allen Kelch, M. D.

The subject for consideration by the Louisville Medical Society at its meeting on Thursday evening, July 10, was "Uterine Reflexes." The discussion of the subject was opened by Dr. Douglas Morton, who read a paper reporting several cases of reflex disorders due to no manifest local disease, and closing his paper with the report of others in which sufficient local structural change existed to account for the reflex disturbance.

The first case reported was that of a lady thirty-five years of age, who had been married fifteen years without having children. In this case the reflex manifestation assumed the form of cerebro-spinal meningitis, the leading symptoms of which were intense occipital headache, opisthotonos, obstinate nausea, and vomiting. These symptoms were so severe in the early part of the attack as to require the regular administration of morphia hypodermically to control them. Paroxysms occurred in which these symptoms were intensified. She had fever at first, but this at no period of the attack exceeded 102° F.

This attack lasted several months, at the end of which time she apparently recovered for about two weeks, when on attempting to walk the symptoms reappeared. There had now been used in the case morphia, hypodermically, the hydrate of chloral, and bromides until they ceased to bring relief. At this time I had one of the physicians who had seen her before to visit her with me, and together we determined to subject her to a course of uterine therapeutics. She objected strenuously, expressing her positive conviction that no disease existed there. She finally yielded, however, and irrigation was at once begun with water as hot as could be borne. This was followed by the application to the surface of the os of the strong tincture of iodine. She had no return of the trouble after the irrigation. After a year of excellent health she had another attack which did not yield to the same treatment. Free discharge was now set up by the application of nitrate of silver, when she was once more relieved. In this case there may have been a genuine cerebro-spinal meningitis in the beginning which, through its influence upon the nervous system, left it in a condition to be easily unbalanced by any existing local pathological condition or irritability.

Case 2 was a woman 45 years of age, and the mother of several children. For more than a year her health had been declining. She had suffered from numbness in the leg, especially at night. She sometimes awoke to find the left limb completely anæsthetic; this caused her to fear paralysis. Beyond this there was no especial prominence of pelvic symptoms. Throughout her life she said she had been unusually healthy in this respect. Constitutional treatment for several months gave indifferent results. Finally, examination revealed but little evidence of local disease. Still, I advised local treatment for a time. I therefore applied iodine, followed by glycerine tampons and irrigation. She still menstruated, but irregularly, and accuracy demands that due prominence be given the influence which the climacteric period exerts over the system. Under this treatment she recovered. It is therefore of no little interest to note that this method of therapeutics enabled us to treat this case with success at this period of life.

The third case was a woman 40 years of age, mother of two children, the youngest of which was six years of age. She suffered from occipital headache for several years, and from dyspepsia; her general health was much reduced. Large quantities of quinine had been used without affording relief. Through the influence of the bromides she had been relieved for a time, but they had now lost their efficacy in her case.

Uterine symptoms were entirely absent. Examination revealed the upper portion of the anterior lip of the os uteri affected with granular erosion. At this point it was exquisitely tender. The womb, however, was but little if any larger than in health. The strong tincture of iodine and hot water injection here afforded relief complete and permanent.

Case 4. A woman 24 years of age had a child two years of age; she suffered from intense abdominal pain, extending to and implicating the stomach. She was treated for a long time by constitutional remedies without relief. She had no backache, no leucorrhœa, nor other pelvic symptom. Digital examination revealed considerable hyperplasia. There was from the beginning of the treatment a profuse discharge from the cervical canal. Relief and general improvement followed, and recovery finally took place.

A young woman, 20 years of age, had been in bad health for several years. Menstruation was painful, and the other pelvic symptoms plainly but not prominently marked. She had long been receiving constitutional treatment without benefit.

Examination revealed anteflexion, with a considerable amount of corporeal metritis. The usual local treatment was applied for three months, when she had found greater relief than she had experienced for years. Her previous long suffering had implicated the stomach, and a considerable experience proves that when this new center of disturbance has been added to that already existing, the results of local treatment cannot prove so satisfactory. Still it is better than that secured by constitutional remedies alone.

The general condition of the subject of uterine disease can, I admit, be improved by tonics and general treatment; but the original disease will surely show itself again, and anything like relief must be sought through the medium of a judicious combination of local and general treatment.

The last case differed from the preceding in that all the pelvic symptoms were prominently marked, and examination revealed a pathological state sufficient to account for any amount of sympathetic disturbance.

A woman, thirty-two years of age, the mother of several children, had long suffered from troublesome dyspepsia, was unable to walk but a few feet, had, as before stated, all the pelvic symp-

toms well marked, and in addition, considerable involvement of vision. Examination revealed not only great enlargement, but also retroversion in a marked degree. The correction of the retroversion and the application of suitable measures to secure the resolution of the hyperplasia afforded relief likewise in this case.

The question must arise to every enquiring mind why the same pathological condition, apparently, existing in some women should give rise to so much disturbance, while by another it will scarcely be noticed? and, again, why apparently identical pathological conditions should give rise to such diverse manifestations in different subjects. In the first place, the identity of pathology may be more apparent than real. As our facilities for investigation increase, differences in this respect may become discernible. It ought likewise to be remembered that under constant irritation and suffering the weakest part of the system will first fail, and the force of depression in these cases brings particular strain upon the nervous system. In some cases the general symptoms seem out of all proportion to the local condition present. Their presence, however, continued may generate real disease; palpitation of the heart, brought about by uterine disease, may result in what is called irritable heart. The spine may be likewise affected. Local treatment, when secondary diseases have become established, will not suffice. The treatment must then, as I said before, be composed of a judicious combination of general and local treatment.

Dr. W. H. Wathen said: "This is certainly a subject in which every physician is interested, because it is to the general practitioner that such cases usually first appear. Unfortunately I did not arrive here in time to hear all of this interesting paper; but if I gather the import of it correctly, the speaker was reporting a series of cases of reflex neuroses resulting from uterine and ovarian disease. At any time during the fruitful period of woman's life she may have manifestations of this kind, but their occurrence is much more to be expected at the menopause. While we are all very much interested in this subject, it is one, unfortunately, which is not, even by the most learned in the profession, very well understood. It is, as has been said by the late Dr. Beard, the Central Africa in medicine, the unexplored wilderness. Yet we know much more of the subject than we did a few years ago.

"I was much interested in the closing remarks, in which Dr. Morton called attention to the widely different constitutional manifestations which result from the same kind of local disease, and the relative excessive manifestation in one patient over another. Often we find in this class of diseases extensive local pathological changes producing in one woman but little general disturbance, while another, perhaps, with an insignificant degree of local change, will be the subject of many and varied constitutional disturbances. We know that the susceptibility to disease of any character is not the same in different individuals; yet we can not always explain why this is so. There is, in other words, in some constitutions a predisposition to the development of disease. So it may be in these cases. A predisposition exists in one individual that does not exist in another. That predisposition may be handed down from parent to child, and obey the general rule of inheritance. This might be styled the transmission of neurasthenia, or impoverishment of nerve-force, a condition that places a woman's system in such a state that it responds by a reflex disturbance to the least local trouble. This reflex neurosis affects especially the ganglionic system of nerves, which supplies all the blood-vessels, even the most minute, so that a little excitement of this system produces certain local congestions. We sometimes see women in whom a little excitement of this kind will produce a local congestion in the face or in some other part of the body; but the structure, above all others, where we find this local congestion to occur, is in the uterus and its appendages. This state of congestion then continuing, results in so-called chronic inflammation and hyperplasia—uterus becoming enlarged and heavy. In this state flexions are much more liable to occur, and pelvic symptoms at this stage are almost certain to manifest themselves.

"To relieve this condition of things there is nothing better than hot water. This should not be used in small quantities for a little time, but large quantities for weeks and months if necessary—from one to two gallons at a temperature of from 95° to 110°. The hot water is locally anæsthetic. At first it causes congestion of the parts, but after a few moments the coats of the vessels begin to contract, its calibre grows less and less, and the parts are left finally in a depleted condition.

"This treatment, persisted in with appropriate constitutional treatment, will often result in a cure of these patients, and no other treatment benefits them so much. The present occasion is not a fitting one to enter into the discussion of massage, which has as its effective principle the relief of local congestion by encouraging the flow of blood to other parts."

Dr. Erwin said: "The ground has been so thoroughly covered in the discussion that it leaves little to be said that is of anything like scientific accuracy. I think, however, we are too apt to refer all reflex symptoms to disease of the womb, forgetting that diseases of other central organs may produce the same kind of manifestations; for example, a middle-aged lady, whose reflex troubles had baffled the skill of several of the best physicians who had examined her and treated her locally and constitutionally, fell into my hands, presenting the usual pelvic symptoms, leucorrhœa, backache, etc., and in the way of reflex trouble, acid eructations, frontal headache, vertigo—in fact, everything that would suggest uterine disorder. An examination revealed an excessive flow from the neck of the womb, which resisted all attempts to relieve it. We examined the rectum, and there found a polypoid tumor attached by a pedicle above the sphincter. It was removed. The leucorrhœa, which had heretofore existed in spite of treatment, ceased of itself, the pelvic symptoms disappeared, and the woman recovered entirely. The intimate connection between these important organs located in the female pelvis should not be overlooked.

"Another case that came under my notice was that of a comparatively young woman, the mother of two children, who had for a couple of years

been suffering from something like monomania. She had no loss of appetite, no constitutional disturbance of any character. She complained of but one trouble, and that was when left alone she felt an irresistible desire to wash her hands and face. She would bathe herself in this way all night long. Otherwise she presented no signs of disease whatever. Upon questioning her why she did this, she said she had a feeling of uncleanliness which the frequent washing relieved, and she could not resist the desire to perform these ablutions. Suspecting that perhaps there might be some local condition to account for this, an examination was made, and revealed an abscess pointing in Douglas' cul-de-sac, which no doubt had been coming on there for two years. This, when relieved, brought relief from the other singular manifestation. There is another case in which the womb was not involved. These cases must not be forgotten."

Dr. J. H. O'Reilly said: "Dr. Morton has spoken of the prominent general symptoms occurring in some cases, and supposed to be due to constitutional disturbances, and treated constitutionally by skilled physicians, which finally come into his hands when his familiarity with uterine disease led him to investigate the uterine region, and there he usually found leucorrhœa and congested if not inflamed cervix, whilst in other cases nothing unusual presented. In the latter cases he has applied local treatment anyhow. Well—ah—I suppose that was done on the same principle upon which a man once highly recommended his dog to be a coon-dog. When interrogated as to why he recommended him to be a coon-dog, he said, 'Well, everything is good for something, and the dog ain't good for nothing else, consequently he must be a good coon-dog.' (Laughter.) So these cases, not being anything else, must be uterine.

"Medical literature teems with the history of such cases as have been recited by Dr. Morton and Dr. Wathen, the development of them occurring upon this inherited or acquired neurasthenia. Such cases are explainable, have been heretofore explained, and we have just listened to an admirable elucidation of them from the lips of Dr. Wathen.

"Regarding Dr. Erwin's assertion that the gynæcologists have the fault of attributing everything to uterine disease, I would say for myself individually that I should certainly not have thought that an irresistible desire to wash the hands and face could have any connection with uterine disease. I should certainly have thought the woman was crazy.

"In another case the gynæcologist would arrive at his diagnosis by exclusion. There are certain head pains in women that have always been recognized as of uterine origin; for example, the bi-parietal pain—this, however, may arise from constipation of the bowels. A persistent occipital pain is almost pathognomonic of cervical trouble. These pains are different from the common neuralgias, both as to the nature of the pain and the recurrence of it. The admonition, however, to be on our guard against infatuation by a special theory or practice, I recognize as timely and well-put. In this situation there may be vesical, urethral, and rectal troubles, and there are an immense number of rectal troubles that give rise to pains closely simulating those characteristic of uterine trouble. So that good gynæcologists, like other good men, are not misled easily.

"I would not disturb the completeness of Dr. Wathen's explanation of the influence exerted by the acquired or inherited disposition or impoverished nervous condition to produce local congestions, and in that way chronic inflammation and enlargement of the uterus. But there is still another explanation that can be given. Dr. Hodge speaks of irritable uterus, a condition of things suggested before him by Bright and Gooch—a theory that has often been opposed, but, to my mind, never yet successfully refuted. There are still other causes concerned besides neurasthenia and irritability. There is a want of good red blood and a want of solid muscular tissue generally in these subjects. Again, there is a periodical congestion of the uterus which normally soon passes away. Should it not do so, however, as sometimes happens, a chronic inflammation is apt to arise as the result of the prolonged congestion. Still, once more, in married women who have given birth to children, a laceration may have occurred, healed, perhaps, completely, yet in the healing cicatricial tissue may contract upon terminal nerve filaments and produce an amount of general disturbance, while no adequate local condition could be discernible through the speculum to explain it."

Dr. Wm. Bailey thought there was being too much examination done entirely. It was the custom, said he, for a man whom most of the members of the Society were acquainted with, to tell a female patient to put out her tongue, and to make the diagnosis of womb disease immediately upon seeing it protruded. So the specialists will look into a woman's throat, and say, "O, you have womb disease."

Dr. Preston Scott said: "I am anxious to hear from the specialists present to-night on this subject, since I have no doubt that most of them have recognized in the disturbed vision of some females reflex symptoms referable to central irritation. While my friend Dr. Bailey makes light of his friend who sees uterine disease in the patient's tongue, it is a fact beyond controversy that other gentlemen now present have recognized from the persistence of disturbances of vision without adequate local trouble to cause them, the probability of their central origin and their manifestation through the sympathetic system. But if we contract our conclusions to one case, we may suppose we have discovered the key to all these nervous disturbances of females.

"There is no doubt of the accuracy of the suggestions made by Dr. Morton, and their application to the series of cases he has reported. There is a larger and broader view, however, to be taken of this subject. While a large number of the symptoms of general disturbance may arise from local causes, yet a large proportion of them arise from disturbances of nutrition. What better illustration have we than in the pregnant female? Now and then we will meet with a case of nervous irritability in a pregnant female whose life will be imperiled by the extreme sympathetic disturbance of the stomach. This illustrates certainly that

the local impression can exert a powerful influence upon the nervous centres. Woman has a ganglionic system more highly organized than man, and as she becomes the subject of various mental nervous disorders this ganglionic system becomes more easily disturbed, and then we find pathological states arising in which the ganglionic system must be regarded as an important factor. Therefore it is that measures of treatment addressed to the general condition alone often result in a cure without resorting to local measures. There naturally arise two conditions or two schools or classes of practitioners. One man looks with a single eye through the speculum, and finds that the only method of diagnosis and treatment; another treats them upon general principles. Happily, both sometimes succeed; unfortunately, both sometimes fail. Weir Mitchell has had wonderful success in the treatment of these neurotic females. In these cases the uterine plexus is greatly disturbed, and with the improvement of the general nerve state, and through that improvement of the blood, local disturbances are often overcome. So I say we must not allow ourselves to fall into the practice of local treatment alone, nor confine ourselves on the other hand to general treatment in all cases. A wise practitioner will remember that these local disturbances are acting upon a ganglionic system already sensitive from improperly performed functions of nutrition. Keeping this in mind, he will give to each its due importance and its appropriate measure of treatment."

Dr. Dudley S. Reynolds said: "I have listened to this discussion with a great deal of interest, and I have been impressed with the idea, as the discussion has progressed, that there are two important points for consideration. They relate to the causes concerned in reflex manefestations; one the disposition or predisposing cause, the other the exciting. The predisposing causes are disturbances of nutrition, which I do not think ought to be regarded as inherited, in that respect taking issue with my friend, Dr. Wathen. Disturbed nutrition is the one essential and never-absent state in all that class of people who have reflex nervous disturbances. Local mechanical conditions, whether from local congestion making pressure upon nerves or effusion, laceration or inflammation, exert their effects more potently then upon this complex and little understood system of nerves.

"Then the first thing it seems to me is to set about the improvement of nutrition. Treatment ought not, I think, be limited to the uterus nor to the rectum, yet they may be regarded as important regions through the medium of which adjacent parts may be inspected. But the mere inspection of the cervical canal, or that the presence of a flush here or an erosion there constitutes the sum total of the trouble, I doubt. Whether the application of hot water does more than to soothe pain, or in that way relieve the irritation, is a question to be settled by clinical experience. I know, as you all do, that distubances of vision are particularly liable to occur in women suffering from flexions. These disturbances are particularly troublesome during the menstrual period. I have a patient under treatment now who has a dry throat, cough, exceedingly sensitive pharynx, even to the presence of food. The laryngoscopic micron allowed to touch the walls gags her, and if persisted in produces emesis. This person is quick in her movements, she does not eat prudently, and bears the other evidences of a neurotic female. She has a flexion of the uterus, and is now under treatment by one of our best practitioners in that special department. If I am correctly informed, flexions of the uterus nearly always give rise to serious neurotic distubances, which are greatly aggravated in married women by a knowledge of the fact that they are sterile. While Dr. Mitchell, of Philadelphia, has done much in the interests of this class of debilitated subjects by studying more closely the subject of irritation, and adding somewhat to our knowledge of the means by which it may best be improved, it yet remains painfully evident that flexions of the uterus are incurable in most cases. Therefore, one of the prime causes of the reflex nervous disturbances made the subject of discussion this evening, it must be admitted cannot, in the present state of our knowledge, be removed, and the field is still open for original research and experiment. Heroic feeding has its advocates, and I am impressed with the fact that better feeding promises more than any local measure yet suggested for the correction of the mechanical causes of hysteria.

Dr. Wm. Bailey: "I want to express myself upon this subject in this way. We should not overlook the fact that woman has nearly the same anatomical formation and nervous system that man has. I believe that there is a tendency upon the part of specialists in this department to attribute too much to disturbances of the uterine function or to uterine disease. I believe we should treat many of these cases just as we treat men. Men may have corresponding or similar disturbances, local changes, for instance, in the throat, not referable to this as a cause; and we should not overlook the fact that general constitutional conditions, departures from normal nutrition, may have much to do with these conditions, when they may be simply concurrent with uterine disturbance. I take it that if you will examine carefully, there is scarcely a woman whose functions in this respect are all regularly performed, or who has not some degree of displacement. Yet, thousands of them will go on enjoying perfect health with these displacements, until their attention is called to them by some specialist in this department of practice. I believe the majority of these cases can be successfully treated by means of improvement of the nutrition, disregarding as far as possible the uterine disease. I think much evil has been brought about in the last twenty or thirty years by the very constant use of the speculum in the treatment of women's diseases. While I am not disposed to disregard many cases that are successfully treated by this local method, I do wish to express myself as decidedly opposed to the very frequent use of local applications. The hot water will often, no doubt, of itself accomplish all that can be accomplished in the way of local treatment."

Dr. Wathen said: "I agree with Dr. Bailey that local applications are often made to the uterus when there is no necessity for it. I have frequently had women come to me desiring to be treated locally, they said, for ulceration. Now,

ulceration very rarely exists unless it is specific or cancerous, and examination has revealed that these women had no ulceration. Thus, one examination made by a competent man is often sufficient to make the nature of the case clear, and the necessity for non-interference in the way of local applications apparent. Instead of specialists, who understand their business, making these frequent applications when unnecessary, it will be found more frequently that it is those opposed to specialism who do it. There are cases in which you might use hot water and almost everything else without doing any good, yet applications of the particular kind required may bring complete and permanent relief.

"As regards the ability of the specialist to determine the probable existence of uterine disease by an examination of the throat, I wish to refer to just one case, though I might cite many others. I very seldom examine unmarried females, yet I do so occasionally. Something like a year and a half ago a young woman from the country came to my office bearing a note from Dr. Kelch, which stated that from the condition of things presented by an examination of the throat, in conjunction with other symptoms, he was led to suspect that trouble of some character existed about the uterus. The young woman presented many of the symptoms of consumption, but none of the physical signs. She had a dry, irritable throat, and a constant cough. A brother had died the preceding year of what was called consumption; and as she was the only living child, her parents grew very anxious about her. I acted upon the suggestion, made an examination, and found an abrasion of the os probably as large as a ten-cent piece. Under appropriate local treatment she soon recovered vigorous health, and remains well to this day.

"Beyond painful menstruation, this young woman presented no pelvic symptoms that would call attention to that region as the seat of disease."

Cases Illustrating Acute Traumatic Malignancy.

As of interest in connection with our recent editorial on the subject, we present the following cases, which Dr. Lambert H. Ormsby publishes in the *Lancet*, July 26, 1884:

Case 1.—B. H., a young gentleman, aged ten, in the month of June, 1869, fell off some rocks at the sea-shore. In falling, he came in contact with a large stone, which struck his right leg about two inches below the tubercle of the tibia. He felt the place rather stiff and painful for two or three days after the injury, which was treated by cold lotions, bandaging, and rest. However, the pain never altogether disappeared, and in about a fortnight the whole circumference of the limb began to swell, and the seat of the injury, on the front of the tibia below the knee, became very painful. He was unable to walk, and began rapidly to lose flesh and appetite. The limb by this time had become considerably enlarged, glazed, and tense, with large blue veins coursing over its surface. About the end of July his father consulted the late Mr. Adams, who recommended that Sir George Porter should also be consulted. At this time the nature of the case was clearly defined, being considered by the surgeons mentioned to be a rapid development of malignant disease of the tibia, at the seat of injury. Amputation at the lower third of the thigh, above the knee-joint, which was already more or less implicated, was suggested as the only means available to save the little patient's life. The father, however, would not consent, but took the child to London, where he consulted Sir James Paget and Mr. Cæsar Hawkins, who also recommended that amputation should be performed. After remaining in London some few days, the father brought the boy back to Dublin, who by this time had become very much weaker and more emaciated, being apparently worn out by the incessant pain and sleepless nights. At the request of the father the limb was amputated at the lower third of the thigh by Sir George Porter, assisted by the late Mr. Adams, Mr. William Stokes, and myself. The boy recovered the shock of the operation, but sank three weeks afterwards from sheer exhaustion. In this case the patient was apparently in the best of health up to the time of the fall, and from that period rapid development of malignant disease (fungus hæmatodes) set in, and he died within three months of the receipt of the local injury.

Case 2.—Robert F., aged twenty-five was admitted to the Meath Hospital from the county of Keary, on March 18, 1884, under my care, suffering from an enormous tumor growing from the left side of the neck. His previous history was as follows: About ten months before he received a severe blow of the fist on the left side of his neck, and from that time he felt pain and uneasiness in the part. A slight swelling soon appeared and grew rapidly till it reached its present dimensions, as depicted by photograph, which was taken while in hospital. His family history was good; none of his relatives were affected with cancer; he has had to work very hard, subjecting himself to much wet and cold. Latterly, he thought, the tumor had increased more rapidly in size, it had become very painful, and he had lost flesh. He had difficulty in swallowing, owing to the encroachment and pressure of the tumor internally on the fauces. Several consultations were held with a view to decide as to the propriety of an attempt being made for its removal. He was exhibited at a meeting of this section, and several members present saw him. However, it was considered advisable not to operate, as the operation would necessitate the removal of the entire lateral aspect of the neck. The patient on hearing the decision regarding his case, left the

hospital about April 24, 1884, for the country, without having any operation performed.

Case 3. Thomas N——, aged forty-nine, was admitted to the Meath Hospital from Roscrea on September 11, 1883, under my care, recommended by Dr. Powell, of Roscrea, suffering from an obscure, doughy, tense enlargement of the lower inner third of the left thigh. In June of last year he was working as a navvy on a railway, where he received a severe blow on the inside of his left thigh, at the seat of the present swelling. The part was painful for a few days, when the uneasiness passed away. However, the limb always remained swollen at the point of injury, and slightly stiff. He received the blow in June, and about the middle of August he experienced great uneasiness, with sharp darting pains through the part. He then applied to Mr. Powell, of Roscrea, who sent him up to the Meath Hospital. On admission, the man was rather debilitated, having lost much flesh lately; his left knee and lower part of the thigh were a good deal swollen, with large blue veins distinctly visible over the surface. As the swelling was rather obscure at first, rest, tonics, and strapping the enlargement with compound mercurial ointment were tried, but with no effect. He complained of the bursting tense pain of the tumor, and thinking there might be some fluid present I accordingly, on October 9, 1883, made an exploratory puncture with trocar and canula, and removed a large quantity of dark-colored bloody fluid, which gave him great relief. But the tumor continued to enlarge rapidly, and the clinical characters of the tumor were becoming manifest, as was verified afterwards by a careful microscopical examination by Mr. Abraham, that it was an ossifying sarcoma. A consultation of my colleagues was held, at which consultation Mr. Wm. Stokes was present, when it was decided to recommend amputation at the upper third of the thigh. The patient on hearing this said he would rather die than allow the limb to be removed. He accordingly left the hospital for the country about October 20, 1883.

On January 3, 1884, the man returned to Dublin, and was admitted again to the Meath Hospital in a very much worse state. He seemed greatly worn out with pain. He said that he was now quite determined to allow the limb to be amputated, as he could no longer endure the pain. The tumor had increased considerably, and its clinical appearances were well marked. Accordingly, on January 7, 1884, I amputated the limb by the circular method at the upper third of the thigh, with full antiseptic precautions, and the man made a rapid recovery, and left the hospital at the end of February last. It was remarkable how quickly he recovered health and strength after the limb was amputated, no doubt owing to the removal of the excruciating pain he experienced in the limb before its removal. He had been perfectly healthy up to June, 1883, when he received the local injury, and from that time the malignant character of the tumor was clearly defined in the course of three months.

Case 4. Frances J——, aged fifty-eight, a farmer from Kesh, was admitted to the Meath Hospital, under my care, on September 24, 1883. On December 10, 1882, during the hard frost, he fell with great force on the point of his left shoulder. It was a little sore at the time, but gave him no trouble till five weeks after the accident, when the shoulder began to swell and grew very painful. He then went to the local practitioner, Dr. Geo. Leeper, who applied anodyne liniments, followed by blistering. This gave him some slight relief, and, acting on his advice, the man went into the County Infirmary at Enniskillen, where he was poulticed and afterwards blistered. He, however, did not improve, and left the infirmary, after remaining there for seven weeks, to return to his home. He then, by the advice of his friends, applied poultices of herbs to his shoulder, which produced suppuration at the part. At this stage, Dr. Leeper was sent for, who made an incision in the tumor and gave free exit to a quantity of very offensive pus, after which the swelling in the shoulder went down considerably, and he felt better in every way. While under Dr. Leeper's care a piece of diseased bone found its way to the surface. Dr. Bagot, of Enniskillen, saw the man at this time, and recommended him to seek admission to a Dublin hospital.

On examination, the contour of the shoulder was found very much changed, presenting an immense lobular malignant-looking enlargement (probably sarcoma), with a tense, semi-elastic surface, resembling a boiled leg of mutton, with large veins coursing over it. The glands in the axilla were also implicated, and became merged into the swelling. There was also a constant discharge of thin sanious pus, from two small openings where the piece of bone was removed. The disease and enlargement extended from the insertion of the deltoid along the clavicle and down the great pectoral muscle, across the anterior fold of the axilla, round the arm, to the posterior fold of the axilla and scapula as far as the attachment of the deltoid to the spine of that bone. On September 26, 1883, two days after admission to the Meath Hospital, a full consultation was held on the man's case. The only operation that could have been performed was amputation at the shoulder-joint, but as the disease had extended to the pectoral muscle on the front of the chest wall, as well as implicating the scapular muscles behind, it was thought such an operation would fall short of removing the entire disease, and further, as the patient was so reduced in strength and emaciated by the constant pain, it was considered that he would not be able to undergo such an operation. Tonics were administered and the shoulder poulticed, and on October 15, 1883, he returned home to the country, where he died a fortnight afterwards quite suddenly, probably from an embolism. In this case the man was in the best of health up to the time of injury, on December 10, 1882, and he died a little over ten months after the accident, of undoubted malignant disease.

The Treatment of Cholera.

Dr. Alexaner Harkin thus writes in the *Lancet*, August 16, 1884:

The disease and its treatment naturally divide themselves into three stages: the pulmonary, or diarrhœal; the stage of violent purging and vomiting and cramps; and that of collapse.

For the diarrhœa nothing in my experience an

swers so well as dilute sulphuric acid, which should be administered every hour in doses of twenty to thirty drops in some agreeable menstruum, with mustard or turpentine epithems to the abdominal region, and iced water when available *ad libitum*. Should the second stage supervene, it is necessary to take decisive steps, lest the third rapidly develop.

It is in the second stage that my peculiar experience becomes available. Physiologists teach that the phenomena of vomiting and purging depend altogether upon the nervous mechanism of the organs affected. According to Michael Foster, "the dilatation of the cardiac orifice is caused, in part at least, by efferent impulses descending the vagi, since, when these are cut, real vomiting with discharge of the gastric contents is difficult, through want of readiness in the dilatation. Since the vagus acts as an efferent nerve in causing the dilatation of the cardiac orifice so essential to the act of vomiting, it is difficult to eliminate the share taken by the vagus as an afferent nerve, carrying up impulses from the stomach to the vomiting centre" (pages 275–6). The influence of the vagus is thus demonstrated in the act of vomiting, both as an afferent and an efferent conductor of nervous energy. Kolman, too, quoted by Hall,* has shown that the right pneumogastric supplies the whole of the small intestines. "This is an inhibitory nerve," he says; "and Moreau and Lauder Brunton have demonstrated that the division of all the nerves going to a portion of intestine is followed by the secretion of a fluid just like rice-water stools of cholera. May not the stimulation," Hall continues, "of the inhibitory vagus be followed by results much the same as if the sympathetic supplying the small intestine were paralyzed?" In accordance with these physiological views, I have latterly treated every case of English cholera in the second stage by remedies applied to the pneumogastric nerve in the cervical region, with the satisfactory result of putting an end at once to the profuse vomiting and purging so characteristic of this stage. Arguing from its controlling effect in extreme cases of English cholera and cholera infantum, which our best authors say differ only in degree from the Asiatic type, I have every confidence that it will prove equally useful should the latter epidemic gain a footing in this country. There is another important indication, which will be subserved by counter-irritation over the vagus—viz., the restoration of the cardio-inhibitory function of that nerve; thus the violent contraction of the heart will be controlled, the expansive power of its cavities restored, and the congestion of the pulmonary and arterial system put an end to. The application I have always used is the epispastic solution of the Pharmacopœia, applied freely with a brush behind the ear and on the neck as far as the angle of the lower jaw. No matter how violent the vomiting or purging, I have never failed in stopping both by this application; a stimulating effect is produced at once, and with it all gastric disturbances cease.

For the stage of collapse, which, according to Claude Bernard, is due to great irritation and hypertrophy of the sympathetic nervous system, Dr. Hall, who has seen a large amount of cholera in India,* proposed to the Royal Medical and Chirurgical Society of London, on October 13, 1874, a plan of treatment which received the approval of the Society, as well as of Sir Joseph Fayrer, who was present. He recommends the subcutaneous injection of a solution of chloral hydrate, 10 grains in 100 parts of water, in four or five different places, according to the size of the syringe. If reaction does not commence in an hour, he injects again. The sedative soothes the contracted nerves, and relaxes the contracted vessels; the blood is once more uniformly distributed, and consequently the pulse reappears at the wrist, the cramps and abdominal pains subside, sleep is induced, the respiration becomes regular, the discharges lessen, the face fills out, the voice becomes stronger, and the natural secretions are restored. Mr. Higginson, in his report to the Deputy Commissioner at Keri, Oude, states that he has treated nineteen cases of cholera according to Dr. Hall's method, of whom seventeen recovered, being about 89 per cent. of cures. For purposes of illustration I append a statement of two cases out of many which I have treated during last autumn.

Case 1. *English Cholera.*—Constable C—— sent for me on September 18, 1883, at 8.30 a. m. I found him in the act of vomiting, with small quick pulse, violent cramps, forcible palpitation of the heart, great debility, faintness, and coldness of the extremities. He was purged at frequent intervals, and the dejections were of the rice-water character. He informed me that when on duty in the police-cells at 4 a. m. that day, he was attacked with profuse vomiting, followed in an hour by violent purging, with cramps, an attack occurring about every fifteen minutes. I did not order him any medicine, but painted him at once in the hollow behind the ears down to the angle of the jaw with an epispastic solution, assuring him that he would not have any return of his symptoms. I visited him again at 10:30 a. m., and found him quite convalescent, not having had any sickness or suffering, as I predicted.

Case 2. *Cholera Infantum.*—On September 24, 1883, I was summoned to see a child living in Upton street, Belfast, aged twenty months, at 11:30 p. m. I found it lying on its face across its mother's knee, with its arms and legs lying listlessly at either side; it was purging and vomiting at the same time. The child was almost pulseless, and was cold and feeble. The mother informed me that it had sickened at 6 p. m., and that it had vomited at least every quarter of an hour till the time of my arrival. She attributed its illness to a mess of soup which it had taken the previous day. She had administered milk with lime water, without any benefit. I did not recommend any medicine, but, having had the child placed on its back, I painted it with the blistering fluid behind both ears, informing the mother that from that moment both vomiting and purging would cease. Soon after the application of the remedy the child began to improve, the heat returned to the extremities, and at the end of half an hour it was fast asleep, when I left for the night. Calling at 10 a. m. the next day, I saw the child in its mother's

*British Medical Journal, vol. ii., 1874, p. 600.

*Ibid., vol. ii., 1874, p. 254.

arms, looking quite lively and well. As I foretold, both vomiting and purging had instantaneously ceased.

There is no need of multiplying examples; these two are the representatives of a great number, irrespective of cases of bilious vomiting and gastritis from alcoholism, similarly and successfully treated.

In the cases related I applied the remedy behind both ears; in several others I found the single application behind the right ear sufficient for the purpose; and this appears to me preferable to the double blister, as, from its powerful inhibitory effect upon the heart as well as upon the abdominal viscera, the modified application is perhaps the safer. In these cases of severe suffering any one can understand the satisfaction that is felt when he is justified in saying, "Permit me to apply this external remedy, and all your troubles will at once depart."

The Use of Antiseptics in Puerperal Cases.

In the *Jour. Am. Med. Ass.*, August 2, 1884, Dr. Madison Reece thus writes:

During one of the hottest days of the month of July, 1881, I was called to see Mrs. W., near London Mills, in consultation with Dr. Wilson, of that place. I found her in a small bed-room, only large enough for the bed upon which she was lying, with but one window in the room. She had been confined a week previously. Her pulse was 160, her temperature 106°, the tongue dry, abdomen distended to the size of a woman at full term, the secretion of milk suppressed. She was delirious, and an odor filled the room like that of a body far gone in putrefaction.

The husband was informed that there was no probability whatever for the recovery of his wife, every symptom indicating a speedy dissolution. However, I suggested a thorough washing out of the uterus with antiseptics. A half gallon of warm water with two drachms permanganate of potash was prepared. After being placed in a proper position across the bed, a gum catheter of the largest size, with several fenestra in the lower end, was passed up into the uterus as far as it would go. A common Davidson syringe was attached to it by means of a piece of rubber tubing. The uterus was thoroughly washed out, the injection being continued until the water returning was perfectly free from all odor and clear in color. The discharge from the uterus was of such a peculiarly strong odor, that it was impossible to free the hands from it. It was like that one acquires in the dissection of bodies.

Such a change as took place in this woman's case within an hour, I never before saw in any case. Immediately after this cleansing process the delirium passed off, the temperature fell, the pulse came down—in short, the effect was simply magical. She was given twenty grain doses of the sulphite of soda. The husband was taught how to administer the injections, which were to be given every three hours—one of a solution of permanganate of potash, the other of carbolized water, alternately. The patient made a speedy recovery from the severest attack of puerperal septicæmia I have ever seen.

Twelve years before this case, in September, 1869, I was called to see a woman who had had an abortion produced by mechanical means. She had a rapid pulse, high fever, hot skin, unquenchable thirst, irregular chills, an icteric countenance, and a sanious discharge from the uterus that smelled horribly.

A half dozen intra-uterine injections of carbolized water, thoroughly administered, rescued her from impending death.

Ever since that time I have used this method in all such cases with similar results, with a few exceptions. They are to be regarded as similar to surgical fever, the result of decomposing *débris* in the uterus, which is absorbed from the uterine surface, and which Sir James Simpson has aptly compared to the flap of an amputated thigh, with its raw and bleeding surfaces, and patulous vessels ready to absorb the decomposing fluids with which they may lie in contact.

The following long-continued case illustrates, in another way, the value of these intra-uterine injections. The last day of January, saw Mrs. M. A., aged 24, living near Hermon, a strong and vigorous woman. She had been confined twenty-four hours previously. The child was dead when delivered, and was so much decomposed that portions of the skin slipped from the body when handled. She had a chill and profuse flooding a few hours before I saw her. The pulse was 140, the temperature 105°, skin hot, tongue dry, and abdomen tympanitic and distended to the size it was before her confinement.

The uterus was immediately washed out with carbolized water, giving great relief to the patient. The injections were kept up every three hours for a week, with the effect of reducing the temperature after every injection. Quinine was freely administered. Thinking, perhaps, that the septic matter was sufficiently removed from the uterus, the injections were discontinued. Within 24 hours a severe chill, followed by a high temperature, announced the absorption of more septic material. The intra-uterine injections were again resorted to, with the same results, diminishing of temperature, and lowering of the pulse. At the end of a week, as there seemed to be so much improvement, they were once more discontinued. Again, in a short time, there was a chill and return of former symptoms. Again we returned to the use of the intra-uterine injections, and kept them up until every vestige of fever had disappeared from the case for several days.

In this case there was no bad odor from the discharges, as in the former cases, and the effect of the injections in arresting the poison of the septic matter was prompt and striking.

Should antiseptics be used in every puerperal case? I believe so, especially as antisepsis has come to be considered as the use of every means of cleanliness, and the prevention of infectious or contagious matters. And just here let me record it as my fixed belief, that thousands of women have come to their deaths from the dirt and other matters under the finger-nails of their attendants. That dirt, the nest of infectious particles scraped from the body of himself, or possibly bathed in the infectious fluids of another person, is conveyed by means of the touch to the abraded surfaces in the puerperal patient, and she becomes inoculated with the virus that causes her death. I believe that any one suffering from a chronic skin dis-

ease, or who is afflicted with a chronic ulcer of any kind, should not attend upon puerperal patients, any more than he who is attending patients with scarlatina or erysipelas. In fact, it is my deliberate judgment that puerperal women should not be attended by the general practitioner at all, and for one I will gladly welcome the day when I can turn over all such patients to well educated and thoroughly trained lady physicians, who will make that their special calling.

Begging pardon for this digression, I would say in conclusion that within twenty-four hours after confinement the use of vaginal injections of carbolized water affords the greatest comfort to the patient, bathing and soothing the neck of the uterus where there may be abrasions or lacerations, and cleansing and purifying the parts. If the discharges become foul in odor, and there is a marked rise in the temperature, then the injections should be *intra-uterine*. One precaution should be borne in mind in prescribing vaginal injections, and that is to have the hole in the end of the pipe or syringe closed. I have in several cases seen a severe and dangerous uterine colic, caused by the injection passing into the uterus through the patulous and open os. In the rubber syringes that are sold for female use, I often prepare the pipe for such purposes by closing the central hole in the end, and enlarging the others in such a way that a backward current is given to the injection.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. R. W. Johnson, of Baltimore, in a reprint from the *Transactions* of the Medical and Chirurgical Faculty of Maryland, relates a case of cryptorchidism, and adds a table of all the reported cases of this rare malformation.

——A neatly-prepared little pamphlet on the feeding of infants has been published by the Mellin Food Co., of Boston, describing the constituents and use of their food preparations. It will be found an instructive guide.

——*Godey's Lady's Book* for October appears with its usual full assortment of pleasant reading for the family. The stories are such as are well suited to the household. It is one of the oldest of our magazines, and is one of the most successful.

——Dr. W. T. Briggs, in a reprint from the *American Practitioner*, gives valuable directions as to the treatment of epilepsy by surgical procedure. His conclusions are as follows :

1. That the operation should be done as early as possible, because the long-continued irritation and interference with the healthy nutrition of the brain and nervous system will often beget a permanent impression, which will remain after the point of irritating bone has been removed.

2. The operation should be thorough and complete, for if all the offending part is not removed no benefit will accrue.

3. The operation should be carefully and cautiously done.

4. The wound should be dressed after the open method.

——The "Transactions of the South Carolina Medical Association," for 1884, fill a volume of 131 pages. It contains the proceedings, the address of the President, Dr. R. A. Kinloch, and a number of original articles in the various departments of medicine, one on the "Sanitary Uses of Plants and Flowers," by Dr. James Evans, opens a subject of wide interest in general hygiene. Dr. T. J. McKie gives a local study of epidemic continued fever, which is instructive. An outbreak of diphtheria is described by Dr. J. R. Bratton. The effects of a poisonous rat bite are described by Dr. W. T. C. Bates. The volume is throughout a creditable one.

——A study of gun-shot wounds of the small intestines, by Dr. C. T. Parker, of the Rush Medical College, Chicago, makes a neat pamphlet of 67 pp. It is illustrated, and gives numerous cases.

BOOK NOTICES.

Visions of Fancy. By N. M. Basket, M. D. Pp. 109. J. H. Chambers & Co., St. Louis.

One always turns to a volume of poetry with suspicion, so much of it being published which had better have been burnt. We do not, however, wish this fate had overtaken this unpretending volume, as it certainly contains several pretty pieces worth reading and preserving. Its spirit is too uncheerful to suit many tastes, and a little of the sunlight of life would have helped it.

Diphtheria, Croup, etc.; or the Membraneous Diseases. By C. B. Galentin, M. D. 8vo., pp. 174. J. H. Vail & Co., New York.

The point to which the writer of this volume gives his especial attention is the treatment of the diseases he names, and especially their treatment by *chloral*. This he has employed in over 400 cases, and has come to look upon it almost as a specific. He administers it constitutionally and locally, and claims the most satisfactory results.

He also gives a quite full notice of the recent plans of managing the membraneous diseases advocated by other writers, and his book will be found a convenient and practical manual on the subject.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,

PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

CANNIBALISM.

We intended at first to refrain from any comments on the published reports of cannibalism among the survivors of the Greely Arctic expedition. But so much has been said on the subject, and the poor, half-starved, and nearly frozen victims of a foolish desire to discover the undiscoverable have been regarded with so much horror, because it is rumored that they were compelled to eat the flesh of their dead comrades in order that they might preserve their own lives, that we feel called upon to express an opinion from a medical standpoint.

While, of course, no one would *choose* to eat human flesh, yet we feel sure that any man or woman, placed in a position similar to that of these poor men, who waited, day by day, hoping against hope, for the rescue that their government should have sent them a year sooner (before any of their party had died), would rather eat the flesh of a human being than die of starvation. It is all very nice for us down here, able to procure all the necessaries of life, to shudder at these reports, for it is almost impossible for us to realize how terrible were the sufferings of this little band. This is not the first time that cannibalism has been resorted to in dire extremity by civilized and intelligent men, for Dr. Aug. M. Tupper, in the *Boston M. and S. Jour.*, September 4, 1884, calls attention to the case of the wreck of the schooner Almon Bird, published in full in the *Boston Sunday Globe*, January 8, 1882. Briefly stated the facts are as follows: She foundered in a gale January 2, 1882, and the crew, or the survivors of them, were picked up some forty miles north of Cape Ann, and brought to Boston by a fishing vessel. The men were exposed for three days and nights in an open boat. All were wet through but the mate, and he was the only one who escaped frost-bite. Three men died in the boat, and one a few days after being rescued, his feet and legs frozen stiff almost to the knees, all his fingers and both thumbs also. The captain's feet were badly frozen, and he lost portions of both of them.

On the morning of the third day, says the cap-

tain, "famishing with hunger and actually dying with thirst, we were compelled to do that which made our hearts revolt with horror. Driven to the last resort, and in an untold agony of desperation, I opened the jugular vein of the second mate, who had been dead about two hours, and we wet our parched lips and throats with his blood, still warm. * * * The draught of blood revived us wonderfully, and it is my earnest belief that it was that alone which saved our lives."

He happened to be one of the physicians who had charge of these men after they were landed, and they all assured him that it did "*revive them wonderfully.*" "It put new life in me," was the way each one expressed himself. Of course they felt delicate about questioning them much, and consequently did not make very particular inquiry, but every one knew it, and no one thought for one moment of blaming the poor fellows, as each heart was filled with pity for the unfortunate men. These men had some food (pilot bread) but no water.

In conclusion, we venture to say that even if these poor sufferers did eat their dead comrades (and it is not yet certain that they did), that there are very few, if any, who would not have done likewise in similar circumstances.

AMERICAN MEDICAL COLLEGES.

That our native institutions of medical learning are forging rapidly to the front, we all know. We speak not of the host of colleges that have been started as money-making concerns, but of those well-established institutions whose reputations are national. There was a time, not many years ago, when it was impossible for a man to procure a first-class medical education in this country. After graduating at a licensed school, he was, of course, entitled to practice, but if he desired to thoroughly educate himself in his profession, he was obliged to visit Europe and study for a time in one of the famous institutions there to be found. But, as we say all this has changed. To-day a man can find in the most famous universities and colleges of his own country, just as good facilities for medical education as are to be found anywhere in the world. Indeed, we imagine that the time is not far distant when we will have European graduates and students of medicine seeking our shores for instruction. We are glad to note that so high an authority as Mr. Lawson Tait, of England, entertains the same views, for at the recent meeting of the Canadian Medical Association he said:

"I might gather further illustrations of that intensely conservative spirit which governs everything English. I might wander into the lines of religion and politics and hundreds of other sources, but I prefer to take one of which I can speak at length and in detail; one upon which I believe, if I read aright the compliment you pay me by asking me to appear here before you, I can speak with some authority.

"In my early days the medical education of a British youth was not considered complete unless he had made a tour of the schools of France and Germany, and, like others, I felt of myself as was said of Proteus:

> "'Twould be a great impeachment to his age
> In having known no travel in his youth.'

"But I wish now that the time and money therein spent had been directed to the western instead of to the eastern continent; and I now venture to predict that ere long it will be to the medical schools of America rather than to those of Europe, that our students will travel, as did the apprentices of old before they settled down to the serious exercise of their craft.

"For many years past I have been visited by numbers of my professional brethren from this side of the Atlantic, many of whom have settled down for days and weeks, and even months, to see my work. I have been overwhelmed by the kindliest invitations to visit this continent, but till now I have never ventured across. This delay is an instance of British conservatism, for it is very little the fashion amongst us to take long holidays. My American visitors have one and all impressed me with their possession of that feature of mind which in England I fear we do not possess—the power of judging any question solely

upon its merits, and entirely apart from any prejudice, tradition, or personal bias. No matter how we may struggle against it, tradition rules all we do; we cannot throw off its shackles, and I am bound to plead guilty to this weakness myself perhaps as fully as any of my countrymen may be compelled to do. I may have broken free in some few places, but I know I am firmly bound in others, and my hope is that my visit to a freer country and a better climate may extend my mental vision."

ANOTHER SIDE OF THE QUESTION.

The Swiss Federal Council has lately made a somewhat startling report to the Assembly, embodying the results of an official inquiry into the liquor traffic, induced by petitions sent up from various cantons for legislation against such traffic, The petitions give statistics which show that the consumption of alcohol in Switzerland is greater per head than in any other country of Europe. Statistics also show that the consumption of brandy among the Swiss is increasing, and that parallel with this there is an increase of mental diseases and an increase of misery and want. In spite of all this, the Council refuses to recommend restrictive legislation. It states that the sale of liquor in Switzerland represents an annual return of 150,000,000f. In one clause of its report, headed "The Advantages of Spirituous Drinks," the Council is outspoken in defence of social drinking. Among other statements, it says: "The practice of social drinking of spirituous liquors brings a cheerful temper into society, effaces the traces of daily labor, opens the heart to other impressions, and is intimately associated with the development of public life. The public house fosters intellectual activity, and is a remedy against misanthropy, egotism, vanity, narrowness of ideas, and extravagance of imagination." The report has taken the country by surprise.

These ideas are, however, not new. The belief that a moderate use of stimulants is necessary to maintain the body at the height of its functions has been that of some of the eminent physiologists.

The arguments they adduce are that those nations who have abstained altogether from stimulants, have never a long power. The Moslems are wholly temperate, but their conquests, though brilliant were of short duration.

There is no doubt that by changing the current of the thoughts, brooding on gloomy topics is prevented by alcoholic beverages. Specialists have for this reason recommended them as a preventive of alienation. The flagging energies of the body are likewise led to take on more vigorous action.

Could a nation be confined to light and pure beers and wines, their advantages would probably more than compensate for their drawbacks. This is just where the trouble lies. Distilled and adulterated liquors are the real and main cause of the evil results of which we see so much. So long as we have no means of guarding against these, our safest course is in total prohibition.

PREPARATIONS FOR PESTILENCE.

The frightful devastation of the cholera in Naples should act as a salutary warning to other cities, both in Europe and America. We may indeed consider ourselves as safe from the scourge this autumn, but there is every probability that the germs which are now known to convey the disease will survive the winter in some of the many localities in which it has now obtained a foothold.

Next summer, therefore, we may look out for a recrudescence of the plague, and an extension of its ravages over a yet wider reach of territory.

So far as can be judged, the principal cause of the excessive mortality in Naples was due to the faulty water supply. It is both insufficient and of poor quality. Travelers are always on their guard against it. It has long been known as one of the causes of the prevalence of typhoid fever in that city.

To parallel such morbific intensity, we must look back to some of the pestilences of the middle ages, when the laws of health were still a sealed book to the masses. So they still are to the people of Southern Europe. The sanitary

condition of both Toulon and Naples has been simply atrocious, if the accounts of the papers can be relied upon.

How completely cold may be depended on to destroy the germs becomes a question of great interest just now. In one epidemic in Russia, the cholera continued its destructive march through the intensity of a winter in that severe latitude. The winters of Italy are short and mild, and would favor the perpetuation of the life of the germ until the spring.

These considerations should influence us not to relax our efforts, public and private, and to employ every means that an enlightened sanitary science suggests to meet effectively the approach of the pestilence in the spring.

The heavy death-rate, about 50 per cent., proves with sad conclusiveness that the therapeusis of the disease has not made any real progress. It was about that at its first inroad in 1832, and in later years. By so much the more should we lay stress on the value of hygienic measures, which have repeatedly proved their preservative power.

Notes and Comments.

The Arrest of Primary Hemorrhage after Amputation.

From the *London Med. Record* we learn that Dr. E. Weibel, in the course of a statistical report of the amputations performed in the Tübingen surgical clinic from 1877 to 1882 (*Mittheilungen aus der Chirurgischen Klinik zu Tübingen*, 1883), alludes to the well-known fact that, after a limb has been rendered bloodless by Esmarch's method, the primary hemorrhage from the smaller vessels and from the capillaries is likely to be very profuse. The muscular structures of the arteries, the contraction of which would otherwise excite considerable constriction of the divided vessels and speedy closure of the smaller branches, seems to be temporarily paralyzed by the compression of the limb and its prolonged deprivation of blood. Hence, as a rule, the necessity of tying many more arteries after elastic compression and after isolated compression of the main trunk during amputation. With the object of showing the number of vessels that are ligatured in amputations with elastic compression of the limb, Dr. Weibel has added to his tables two returns giving the number of ligatures applied before and after the removal of the elastic band. These tables show in the first place that the number of vessels to be secured varies extremely even in the same parts of a limb. Thus in amputations through the forearm the smallest number of vessels to be secured was 9, and the largest number 25; in the arm the numbers vary between 15 and 30, in the leg between 7 and 68, and in the thigh between 17 and 67. The average numbers of ligatures applied in the major amputations were as follows: In amputation of the thigh (46 cases) 38.1; in ampntation of the leg (65 cases) 24.3; in amputation of the arm (6 cases) 22.5; in amputation of the forearm (7 cases) 15.7. The following are the average numbers of ligatures applied before and after the removal of the constricting band: Amputation of the thigh (39 cases) 25.1 before, 14.9 after removal; amputation of the leg (49 cases) 15.3 before, 8.1 after removal. The number of ligatures it is found necessary to apply increases, as a rule, together with the thickness of the segment of the limb at which the amputation is performed. Thus, in amputation through the lower third of the leg (47 cases) an average number of 20.9 was needed; in the middle and upper thirds (18 cases) the average number was 33.2; in the lower third of the thigh (27 cases) 37.3; in the middle and upper thirds of the thigh (19 cases) 39.3. Dr. Weibel recommends, as the best means of arresting the free parenchymatous hemorrhage that follows the removal of Esmarch's constricting ligature, elevation of the stump and compression of the flaps by a large sponge previously cleansed by a carbolic acid solution. The application, with the same object in view, of compresses saturated with oil of turpentine, has also been followed by very good results.

Bacteria in the Intestines.

To discover the germs of disease in the alimentary canal, it is necessary to be acquainted with these microbes, which are always met with in the intestines. Prof. L. Brieger, in Berlin, has made a special study of this subject, and published the results of his investigations in the *Zeitschr. f. Physiol. Chemie*, 1884, vol. 8, p. 306–311. From this interesting article we take the following notes:

The coccus of the fæces is found in large quantities. It has about the size of the coccus of pneumonia, and is frequently met with in the form of diplococci. Cultivated on Koch's beef-tea

gelatine, this coccus grows in the form of flat, whitish pyramids; it develops as well on albumen as on hydro-carbons, but better at the temperature of the blood than at that of a room. Injected into the circulation of animals, the coccus proved itself perfectly innocuous.

In combination with this coccus one often finds two species of bacilli, possessing very characteristic peculiarities. The one kind, of varying size according to the length of its existence, causes the gelatine gradually to become fluid, and imparts to it a greenish, fluorescing color, very similar to that of eosin, the coloring matter dissolves in an alkaline solution, and is easily destroyed by acids. More important for the organism is the other bacillus, appearing in the form of very minute rods, and growing in the same culture-soil as the coccus, but in the shape of irregular, concentric rings. Injected into guinea-pigs, they cause their death within 24 hours. A few hours after the inoculation, the animals lost their appetite, became quiet; their respiration was stertorous and dyspnotic, the action of the heart increased in frequency, and the animals suddenly dropped down dead. But if these bacilli were introduced into the alimentary canal of the animals, by being swallowed by the food or injected into the rectum, they caused no symptoms whatever. Rabbits and mice were not affected by them. In the blood of guinea-pigs, that died in consequence of the introduction into the circulation of these bacilli, the latter were always found in great numbers.

Hæmaturia in Cancer of the Kidney.

Dr. A. Seibert has published a valuable contribution to our knowledge of cases of cancer of the kidney in the *Jahrb. für Kinderh.*, vol. xxi., H. 3. Besides mentioning one case of his own in detail, he gives a short description of fifty more cases collected by him, from which we may draw the conclusion, that male and female children and the right and the left kidney are equally often affected with cancer.

Infants suffer most frequently; seldom children after the fifth year. Jacobe is of the opinion that in cases of infants the cancer of the kidney is born with them, and usually develops itself most rapidly in the second half year. The diagnosis is based upon a kidney-tumor, emaciation, pains, frequent vomiting after meals, and early appearance of hæmaturia.

Bloody urine in cases of calculi and of kidneys in the state of caseous degeneration is rarely met with, is then not so profuse, and the blood not so pure, being mixed with mucus, pus, epithelium, and gravel. The pain of cancer of the kidney is not intense, appearing more as a heavy pressure; severe seizures or colampsia, as in colic, never happen. With the appearance of blood in the urine the pain at once ceases or becomes much milder. In cases of inflammation of a kidney we have at times hæmaturia, but here the quantity of the urine is lessened, and the bloody discharge ceases simultaneously with the phenomena of inflammation. Should, in case of cancer, inflammation of the healthy parts be added, there is an increase of the blood-flow, while the quantity of the urine increases, and symptoms of obstruction are wanting. But should the first hemorrhage appear after the commencement of the sympathetic inflammation of the non-cancerous kidney, the hemorrhage then taking place is very sudden and copious. While these hemorrhages are very frequent in cases of cancer of a kidney, they never by themselves cause a fatal issue.

A Case of Homicide by a Wound of the Vulva.

Dr. F. W. Draper reports a most interesting medico-legal case in the *Boston Med. and Surg. Jour.* for September 4, 1884, wherein within the space of five hours (taking outside limits of time) a strong, plethoric, and healthy woman bled to death by a wound of the vulva an inch long and half an inch deep. Such an occurrence, if standing alone as one observed for the first time, would be regarded as extraordinary, perhaps as incredible; but it is fortunate in being in accord with similar observations recorded in surgical and medico-legal writings. It is really a typical example of an interesting class. Ogston* quotes the case of a woman who died in ten minutes after receiving two wounds about the genitals, one on the left labium and the other at the entrance of the vagina at its upper part; the fact that she was pregnant, and that the vascularity of the parts was thus increased, may have had some influence upon the rapidity of the hemorrhage. Taylor† alludes to the case of a woman, eight months pregnant, who "fell from a chair, which also fell with her. There was hemorrhage, and she died in a quarter of an hour. The blood had flowed from a wound an inch and a half long, situated between the right labium and the urethra." In another case "a contused wound of the clitoris proved fatal. A woman, aged thirty-six, received a kick from her husband in the lower part of the

* Lectures on Medical Jurisprudence, p. 486.

† Principles and Practice of Medical Jurisprudence, i., p. 677.

abdomen while she was in a stooping posture. When seen, in about three quarters of an hour, she had lost from three to four pounds of blood; she was sinking, and expired a few minutes afterward. The wound was at the edge of the vulva, extending along the ramus of the pubes; it was about an inch long and three quarters of an inch deep. The left crus clitoridis was crushed throughout its length." These cases are of use in teaching the medical witness that, whether in the presence of a jury or elsewhere, he should be economical in the use of terms like "impossible," or "incredible," or "inconceivable."

In the case reported by Dr. Draper, the jury found a verdict against the husband.

A Case of General Idiopathic Atrophy of the Skin.

Before the last meeting of the American Dermatological Association, Dr. W. A. Hardaway read a paper on a case of this nature, and exhibited photographs illustrating the case.

The patient was a blind man, twenty-three years old. He had a sister also blind, and with the same skin disease, as he stated. The skin of his face was thickened and reddened, there were scars around his mouth, and he had the so-called "strumous lips." The integument of the trunk presented a checkered glistening aspect; patches of pigmented skin alternating with atrophic spots. The skin over the latter was tense and glistening, and could be picked up with difficulty. No dilated vessels were visible. The skin and muscles of the hand were atrophied, and the sides of the fingers had grown together over half their extent. There was necrosis of the conjunctivæ, corneal opacities and adhesion of the lids to the globes.

Dr. Duhring said that the atrophy was the only essential feature of the disease under consideration. All grades are met with, from those having no tendency to degeneration to those developing carcinoma or sarcoma.

Dr. Taylor said that in his opinion the condition of the skin in the case described in the paper was not like that met with in the disease known as angioma pigmentosum et atrophicum, as this patient presented simply an ill-nourished senile-like condition of the integument.

Theories of Color Perception.

Dr. Swan M. Burnett, of Washington, D. D., elaborately discusses in the July number of the *American Journal of the Medical Sciences*, the various theories of color-perception, and points out that none of them accounts in a consistent manner for all the phenomena normal and abnormal colored-vision, and that, moreover, there are certain objections on physical grounds which, with our present knowledge of the laws of molecular and wave-motion, are insurmountable. He advances a theory which he thinks meets the requirements of the case in the light of recently acquired knowledge. He holds that it is essential to do away with the idea of the retina as a differentiating organ, and that it should be looked upon simply as receiving and transmitting structure which shall give up faithfully to the optic nerve the impressions made upon it by the waves of the luminiferous ether. These impressions are carried by the nerve to the brain, and are there properly differentiated and converted into sensations. He believes that by this means all the phenomena of color-perception and color-blindness can be explained in a natural and consistent manner, without the necessity of imagining new tissues, or novel or unusual reactions of these tissues to light. Dr. Burnett considers the retina to be a substance whose ultimate structure is such as to allow it to respond at one and the same time to a large number of ethereal vibrations; at least such a number as shall be represented by the clearly distinguishable colors of the spectrum.

His theory, Dr. Burnett holds, explains the phenomena of defects in color-perception, and receives support from biology and embryology.

Tubercle Bacilli in Urine and Kidneys.

In the meeting of the Berlin society for internal medicine, June 30, Dr. Mendelssohn presented a specimen of the urine and the kidneys of a patient who had been attended several days in the surgical clinic of the University of Berlin for incontinentia urinæ and bladder trouble. On account of a beginning lung affection, discovered the fourth day, he was transferred to the medical ward, where two days later he suddenly died of meningitis. The urine was scanty, opaque, and of alkaline reaction, and contained besides albumen a sediment with light-red clouds, which on nearer inspection were determined to be tissue-debris. The evaporated residue of this urine was examined under the microscope, and found to be full of tubercle bacilli. Their presence in the urine has already been mentioned by Lichtheim and Rosenstein. Very interesting were the grouping of the bacilli and their collective accumulations. Koch, in his most recent communication on the etiology of tuberculosis, has described the type of the growth in pure cultures of tubercle bacilli as elegant figures with various snake-like shapes, the smallest of them resembling the

Roman S. Exacty the same forms are met with in the urine of the patient above mentioned, and also in the pus contained in the kidneys. The microscopical examination *intra vitam* had determined the diagnosis of uro-genital tuberculosis, and recognized its violent form on account of the great number of fresh bacilli. The rapidly fatal issue of this instructive case proved the correctness of the diagnosis.

A Suggestion Concerning the Treatment of Acne and Acne Rosacea in the Male Subject.

At the last meeting of the American Dermatological Association, Dr. S. Sherwell read a paper on this subject. He said that too little attention had been paid to disturbances of the genital tract as causes of the diseases which formed the subject of his paper, and gave credit to Piffard and Hyde for having recognized their importance in this regard. He then spoke of the occurrence of chronic congestion and hyperæsthesia of the male urethra in some cases, and recommended for its relief the use of cold steel sounds. He concluded by detailing two cases which were greatly benefited by this means.

Dr. A. R. Robinson thought the suggestion a ensible one, and if followed benefit would result in some cases.

Dr. G. H. Fox spoke of the liability of physicians to ascribe results to a certain line of treatment, when the improvement might have been due to a change in regimen on the part of the patient without the knowledge of the physician. He also thought well of Dr. Sherwell's suggestion.

The Treatment of Gonorrhœa.

The treatment of gonorrhœa to-day still consists mainly of injections of astringent solutions, sulphate of zinc, acetate of lead, and nitrate of silver being the most common.

Since, however, recent investigations have demonstrated the fact that the discharge of pus is due to the presence of bacteria, the attention of physicians has been drawn to disinfectants and their employment in this disease. The latest report on this subject comes from the *Allg. Med. Centr. Zeit.*, which in its number of July 5, publishes an article of Dr. Kirchbaur, who as a surgeon in the Regular German Army had sufficient opportunity to try the effect of disinfectants in gonorrhœa. He used a four per cent. solution of boracic acid for injection, and in each of the cases he mentions in detail, he succeeded in stopping the purulent discharge by the fourth day, when it gave place to one of a mucous character, which totally ceased by the end of the second week. As boracic acid can do no harm, it may be well worth a further trial in this obstinate complaint.

A New Observation Concerning the Patella Reflex.

Dr. Baierlacher, in Nurnberg (*Centrlbl. f. Nervenh.*, June 1, 1884), has made an observation regarding the patella reflex, which may be of diagnostic value. In a man æt. 55, suffering from neurasthenia and for years accustomed to the injections of morphia, the remarkable discovery was made that the knee-phenomenon was totally wanting without the existence of any symptom indicating locomotor ataxia. For a few minutes after each injection the patella reflex was present and could be plainly distinguished, but it soon ceased and continued absent until the next injection was made. This observation agrees with that of Heinrichs, who noted that before the total disappearance of the patella reflex during chloroform-narcosis the symptom becomes exaggerated for a short time. These facts would tend to prove that the phenomenon is not caused by direct muscular irritation, but is totally of reflex character.

Hepatic Albuminuria.

Dr. C. C. Thayer thus concludes a paper in the *Med. Record*, August 2, 1884 :

1. Crude albumen in the circulation may be excreted as such by *healthy* kidneys.

2. Crude albumen in the circulation may arise from a retrograde metamorphosis of albuminoids in the process of digestion and assimilation from liver *disease*.

3. Crude albumen in the circulation may arise from a luxus consumption of albuminoids in excess of the capabilities of a *healthy* liver.

4. Crude albumen in the urine denotes that albuminose, in its hidden course to its legitimate and ultimate end, viz., fat and urea, has escaped its proper destiny as an aborted proteid.

5. Crude albumen in the circulation denotes not a defective metamorphosis of tissue, for it has never been tissue, but a defective metabolism in tissue construction.

Fatal Case of Hydrophobia.

The *Courier Medical* describes a fatal case of hydrophobia from the bite of a dog evidently not rabid. The patient had been bitten slightly about three months before his admission to the hospital, by a pregnant bitch which was not mad, and which had since brought forth and suckled a litter of puppies. The owner of the animal ad-

mitted that this bitch when pregnant was evil-disposed, and attacked men and animals, whilst she had never been mad nor otherwise ill. The fear of hydrophobia was evidently not the cause of the symptoms observed, since the patient attached no importance to the bite which he had received, and did not even connect it with his illness. The writer adds that "it is prudent to mistrust dogs and cats when in the state of heat or of gestation, and when sick, and also when they become quarrelsome."

Diphtheritic Nephritis.

Apropos of this subject, about which we have already had something to say, we note that Professor Joseph Fischl read before the German Medical Society of Prague a communication on diphtheritic nephritis. He observed that the epithelium is always swollen and fatty. The lesions are always accompanied by lesions of the stroma. Dr. Fischl has found in nine cases out of ten of interstitial nephritis, especially when subcapsular, that the Malpighian bodies are attacked. He also found vascular lesions, periarteritis, and desquamation of the epithelioid lining. He never observed micro-organisms, although his investigations were conducted with the greatest care, and the most perfect optical instruments were used. A number of microscopic preparations and drawings were shown in support of his assertions.

The Etiology of Cancer.

Dr. J. H. Stallard speaks wisely when he says, in the *Pacific M. and S. Jour.*, July, 1884:

No subject presents a more hopeful field for the conjoined action of the profession. We want a more exact personal history of those who suffer from malignant disease, especially as regards the great questions of diet and regimen; and it is much to be hoped those physicians in England and America who have promoted this mode of investigation, will take up this great and important subject. It is now settled that our best remedies are failures, and that early extirpation is our best resource. If we should be able to attack our enemy by preventing the predisposing condition, there will be hope that the cancer mortality will fall.

Tic Convulsif Cured by Stretching of the Facial Nerve.

A woman, æt. 37, had been suffering for eight years from tic convulsif of the right side. All treatment had been in vain. Dr. G. Zesas, who reports the case in the *Weiner Med. Woch.*, 2, 1884, divided, under the carbolic spray, skin for a distance of 4 cm., beginning at the ear, and searched for the nerve behind the organ, and found it without trouble and without serious bleeding after separating the soft parts. Having isolated the nerve he stretched it five times in its centre, and also peripherally. The wound was closed by catgut, and healed by first intention. On the fifth day after the operation, which was performed November 16, last year, the pains became much less, and ceased totally January 4, when the patient was discharged as cured. She has since not suffered from the complaint.

Treatment of Cholera.

The *London Med. Times*, August 2, 1884, tells us that Professor Hoyen has just published an elaborate lecture in the *Revue Scientifique* on the treatment of cholera, in which he chiefly advocates ipecacuanha and opium in the earlier stages, and black sulphide of mercury, with salicylate of bismuth, in the more advanced periods. When the patient falls into the state of algidity and collapse, the professor recommends the intravenous injection of the following solution:

Aq. simpl.,	1,000 parts.
Chloride of sodium,	5 "
Hydrate of sodium,	1 "
Sulphate of sodium,	25 "

A Good Tooth Paste.

Dr. A. W. Harlan, of Chicago, recommends the following in the *Dental Cosmos*, September, 1884:

℞. Precip. chalk.
Powd. orris root, āā ℥ij.
White castile soap,
Powd. borax, āā ℥ss.
" myrrh, ℥ii.
Honey and glycerin, q. s. to make a soft paste.
Color rose pink.
Perfume to suit.

To be used before retiring and after breakfast, on a brush not dipped in water and not too stiff.

The Use of Aperients in Scarlatina.

Commenting on some cases wherein calomel had been given to patients suffering from scarlatina, and where the reports the next day say that the patients passed restless nights, Dr. Edward Wells writes to the *Brit. Med. Jour.*, July 12, 1884, that in his experience, the administration of even the mildest aperient during the eruptive stage of scarlatina is liable to be followed by the gravest symptoms. He should be glad to learn the opinion of the profession on this point.

Correspondence.

A Case of Elephantiasis Arabum.

Eds. Med. and Surg. Reporter:

After graduating from the College of Physicians and Surgeons, Baltimore, the writer began the practice of physic in a city not a thousand miles from his alma mater. His shingle had not been extending a cordial invitation to the public many days before he had a caller. A messenger bearing an urgent message from Mrs. G., who was suffering from erysipelas, caused him to go forth with professional haste and cheerfulness to conquer. Arriving at the house of his benefactor, he was ushered into the presence of an elderly woman, who was seated in a rocking chair with her feet on a chair in front of her.

Nothing unnatural attracted his attention in her appearance, nor did the patient hint at the character of the mystery concealed under her petticoats. She described with exasperating minuteness the suffering she had endured with patient fortitude from chronic erysipelas of the right leg, and when in the course of the morning a request for an examination was inserted into the current of conversation, she drew up her skirts and showed the most remarkable-looking object that was ever attached to a human body. The limb was about three times its natural size, and covered with a scaly black crust, which was seamed and fissured like oak bark or alligator's skin. To say the physician was surprised would but feebly express the condition of affairs at that moment; he had been led to believe from the meagre amount of space allotted to the subject in text-books, and also from the cursory glance given it by the professor of dermatology, that cases of elephantiasis were like angel's visits. However, with a desperate effort to look as if he had taken a dose of *fl. ext. Solomon's wisdom*, the disciple of Esculapius proceeded to investigate the subject. From Poupart's ligament to the ankle joint the limb looked like a charred log, no vestige of comeliness remaining. At the folds in the loins were surfaces presenting the appearance of *eczema madridars*, and in this region the limb measured many inches in circumference; and all resemblance of a joint was obliterated by the product of the lymphatic hypertrophy. The lower boundary of the swelling was clearly defined, overlapping the foot, and leaving raw edges, which were the seat of intense itching and irritation.

The case was an interesting one, and afforded ample room for speculation and experiment. Gross and Reynolds gave the history of the case with surprising faithfulness, and during frequent visits a pretty full account of the case was obtained from the patient. The woman was fifty-six years of age, had been married twice, and was the mother of nine children. Her disease had commenced when she was about fifteen years of age, and was attributed to menstrual disorders, which may or may not have been the cause—in Copland's Dictionary a case is reported caused in that way. The usual course of inflammatory swelling, gradually subsiding to recur at irregular intervals, each time leaving the limb larger, was observed. A crop of scales always accompanied an outbreak, lasting several months. When she was twenty years of age, she was married the first time, and was frank enough to state that the diseased member had never given her husband any trouble. Only since her climacteric has the leg become so unwieldly as to interfere with locomotion. About eight years ago, while on a visit to a town forty miles distant from home, she had fractured the femur in the middle third, and from that time, though the bone united firmly with the formation of a large amount of callous, she was constantly worried with pains and aches. An ointment of pyrogallic acid acted very kindly in healing the denuded surfaces, and in the course of two months the patient exfoliated the scaly covering, and the limb, though enormously enlarged, assumed a semi-human appearance.

At the present time the woman is failing rapidly, and her prospect for length of days is not at all bright. On one occasion not long since, during convalescence from an attack of malarial fever, her limb became covered with purpura hemorrhagica, and she exhibited more alarm than she was ever known to have shown in her life.

This case is not reported with the idea of adding to the stock of professional knowledge, by any means. All that the writer has in view is to impress upon the minds of young physicians that they are liable to be called upon to do anything, from pulling a tooth to holding a post-mortem.

Text-books rear bounds for diseases that are often not observed, and professors often lay down laws which it is some poor unfortunate's luck to see broken early in his career.

Elephantiasis is a native of warm and damp climates, or rather those liable to sudden and violent atmospheric changes; but occasionally susceptible individuals are met with in our own country who have the diathesis suited to its development, and our patient at least had the diathesis in her right leg. While the study of the disease may be unprofitable because of its rarity and incurability, it is nevertheless interesting on account of the deformity it causes; and no matter how fabulous reported cases may appear in the future, the writer will be tempted to believe them.

Emporium, Pa. J. E. Free, M. D.

A New Method of Covering Bone Denuded of Periosteum.

Eds. Med. and Surg. Reporter:—

Some years ago I was called to see David K——, aged about twelve years, who was severely injured by being run over by a heavy wagon. The boy was thrown in the gutter, and the wheel passed over the left side of the head, tearing away the scalp and periosteum, and exposing the skull for a little over one-third of its extent. The boy was carried home in an unconscious condition, and was kept quiet.

In the morning a cathartic was given to act on the stomach and bowels, as a revulsive to the brain. Strange to say, after consciousness returned the next morning, no more cerebral symptoms appeared, and there was very little constitutional disturbance.

But the great trouble was, what to do with the denuded bone, as the scalp and periosteum were ground from the skull and mixed with the mud in the gutter.

Here was an unpleasant dilemma to be placed in, and one difficult to solve. I washed off the mud and blood, and used water-dressing to the head, and covered the denuded part with oiled silk. The inflammation was slight compared with the extent of the injury, and in a short time was subdued, the edges presenting a healthy granulated appearance.

But how was the exposed bone to be covered? If the periosteum had been left, the task would not have been so difficult.

An idea presented itself to my mind, which I have never seen or heard of being put into practice. I had the scalp shaved, and with a chisel cut away the outer table of the skull on opposite sides of the denuded part for about two lines in width, and with adhesive plaster drew the granulated surfaces over the chiseled parts, and to my best wishes had the pleasure to see them insinuate themselves into the diploë and adhere.

This method of chiseling was continued until the entire surface was covered, which took about three months to complete it.

The exposed bone was painted with glycerine and covered with oiled silk, to prevent exposure to the atmosphere as much as possible. The result was very satisfactory, and the cicatrix which was left was small, being less than two lines in width.

The nature of the case and its happy termination, is the reason for bringing it to the notice of the profession, in the hope that in similar cases the above method, if adopted, might lead to as satisfactory results. JAMES CRAIG, M. D.

Jersey City, N. J.

Another Monstrosity.

EDS. MED. AND SURG. REPORTER:—

Noticing Dr. Gardner's "Monstrosity" in last week's REPORTER, induces me to briefly report a case which recently came under my observation.

Mrs. N., aged 38, mother of six healthy children, was confined at 2 o'clock a. m. Found, when called soon after, a well dilated os, vertex presentation with tendency to glide above the pubic arch. After twelve hours ineffectual labor (during which convulsions occurred), introduced blunt hook—fœtus being dead—and drew down the head, when delivery was soon completed.

The head was well and normally developed. Cervix measured ten inches in length. Upper extremities almost a perfect representation of the front legs or arms of the turtle, with palms turned outward. Body broad and flat. Lower extremities much resembling the hind legs of a dog with talipes varus. The cervical vertebræ were of the proper number, but abnormally developed, while the osseous structure of the extremities were simply indescribable.

The only cause assigned by the parents for this freak of nature was the fact that the husband, being a farmer, was the owner of a large flock of sheep, and the ewes dropping the lambs during a cold, damp period, the lady herself during this period, which was soon after her conception, nursed, cared for, and handled a number of the young lambs, feeding them until they were strong enough to follow the herd.

J. F. RICHARDSON, M. D.

Harper, Iowa, Aug. 28, 1884.

Calculus in a Boy Aged Four Years.

EDS. MED. AND SURG. REPORTER:—

I saw the report of a case of calculus in a boy five years old in your last issue. Suppose it was reported because of the age of the patient.

In 1882 I reported a case to the *Indiana Medical Journal* of a calculus in a boy aged four, which came under my observation while assistant physician at the Indianapolis City Dispensary. The patient was colored. Was consulted by his parents because of his frequent and painful urination, which condition they said had existed since the child was old enough to complain. He had been subjected to all manner of medication, and even circumcised, without relief. Suspecting calculus, I examined the bladder with an ordinary probe properly bent, detected the stone, and subsequently Prof. Jos. Eastman removed it by lateral lithotomy. The stone was about an inch and a half long. The patient made a hasty and complete recovery. G. A. COBLE, M. D.

New Augusta, Ind., Sept. 3, 1884.

NEWS AND MISCELLANY.

A Too Hasty Diagnosis.

From a foreign exchange we note a case that carries with it a very strong moral. It appears that the plaintiff in a suit recently on trial in England, a Mr. Yarndley, whilst on yeomanry duty in June last, became saddle-sore, a circumstance by no means uncommon to persons not in the habit of riding much. In order to protect the abraded skin he applied a handkerchief to the part. On his return home, his wife, not being satified in her mind as to the origin of the blood-stains, took the kerchief to a local practitioner (Dr. Pike), who pronounced in favor of the husband's misconduct. Nor did he retract his expressed opinion after he had personally examined the plaintiff, at the invitation of the latter. Horrified at the charge made against him, Mr. Yarndley sought the advice of several doctors in the neighborhood, who unanimously declared that the diagnosis made by Dr. Pike was incorrect, and, with true professional courtesy, advised him to withdraw it. For some reason or other Dr. Pike failed to do this; hence the action brought by the plaintiff, to clear his character from the aspersions cast upon it. Apart from the fact that no manner of stain upon clothing could in itself be taken as proof of venereal disease, the circumstances were strongly suggestive of what was no doubt the real explanation, for the wound on the thigh exactly corresponded with the blood-marks on the trousers. We do not for one moment suppose that the defendant acted from vindictive motives, nor without a *bonâ fide* belief in the accuracy of his diagnosis; but for all that, if the evidence can be relied upon, he showed a lamentable want of forethought and discretion, both in the first instance and afterwards, when his position was shown to be untenable. He ought to have carefully weighed every available fact, and acted with the greatest caution before venturing to give an opinion which would, in all likelihood, destroy the happiness of a home and leave the hapless husband under the stigma of immorality.

It was to be regretted that the case was allowed to proceed to trial, but we are glad to state that the plaintiff was honorably cleared.

Signals to Note the Approach of Marked Changes in Temperature.

The Signal Service of the United States has taken measures to notify of the approach of marked changes in temperature by a system of signals. The "cold-wave flag," white with black centre, will be displayed at the central station, and it is suggested by the chief signal officer that smaller flags (to be procured by individual contributions, as the department has no money available for such uses) be shown at all places to which the *Farmer's Bulletin* is now supplied. The advantage of a general warning of thermometric changes to many industries and interests is obvious.

Mississippi Valley Medical Society.

The Mississippi Valley Medical Society will hold its annual meeting in Springfield, Ill., September 23, 24, 25, and 26. This is the old Tri-State Society organized about ten years ago, but at the meeting last year changed to the present name, through earnest solicitation of adjacent territory, to increase its boundaries.

It is hoped that a large number of the profession in the valley States will participate in an active way at the coming meeting.

Items.

—Doctor (engaged six months after the death of his first wife, soliloquizing over a letter)—"This is better. She addresses me as 'darling duck.' My first wife used to speak of me as 'old quack.'"

—In the *Lancet*, August 9, 1884, Mr. Sydney Jones reports a case of bony anchylosis of lower jaw, with removal of a wedge-shaped piece of bone on each side, and recovery, with good movement of jaw.

—The French method of administering castor-oil to children is to pour the oil into a pan over a moderate fire, break an egg into it, and stir up. When it is done, flavor with a little salt, or sugar, or currant jelly.

—To prevent grating the teeth during sleep, a correspondent of the *Dental Cosmos* says that a rubber plate, made thin, and covering the molars and bicuspids above, and used during the night, has proven very efficient in his practice.

—In order to make a plaster set quickly, mix it with water into which a little sulphate of potash has been dissolved; to make it set slowly, mix it with fine slaked lime. The time of setting may be regulated by changing the relative quantities.

—"What is that invisible power," asked an Austin (Texas) Sunday-school teacher, "that prevents the wicked man from sleeping; that causes him to toss about on his pillow; and what should he do to enjoy that peace that passes all understanding?" "Go to the drug-store and buy some insect powder. Ma sent me for a dime's worth last Wednesday, and we haven't felt——" Johnny Spilkins would have gone into particulars if his sister, who is a little older and has ten times as much sense, hadn't pulled him down.

—A subscription has been opened at St. Petersburg, Russia, in order to raise funds for instituting at the University five bursaries in the name of Charles Darwin, to be employed for the maintenance of five students in the five chief branches of natural science.

—The mortality of the globe, as given by a continental journal, which has made the computation, is as follows: Per minute, 67; per diem, 97,790, and per annum, 35,639,835; whereas the births are 36,792,000 per annum, 100,000 per diem, and 70 per minute.

—The *National Druggist* calls attention to some bad effects following the application of iodoform externally, and attributes them to adulteration with picric acid, which it says is largely used for that purpose. The subject is important, as iodoform has grown into extensive use.

—In consequence of the extension of irrigation works in the province of Rajputana, in India, and the opening of the Rajputana-Malway railway, rendering the produce easy of access to Bombay, poppy cultivation has been constantly on the increase within the last two or three years.

—To overcome a repugnance to the odor of chloroform in certain patients, Prof. Nussbaum, of Munich, has a few drops of oil of cloves placed on the towel before giving the anæsthetic. The addition of one part to six of cologne to ether, makes it much more easy of administration in some cases.

—"Pasteurized" beer is now being sold in Canadian cities. The process of Pasteurization requires the heating of the liquid to a point sufficient to destroy the vitality of yeast cells and other germs. This is accomplished by a temperature over 131° F., and the heat should be applied for a considerable time. If the process is imperfectly performed, the cells will develop as soon as circumstances are favorable.

—Dr. A. A. Willcox, of Cleveland, Ohio, writes to the "Dental Cosmos" that the severe pain which often accompanies the application of arsenious acid for the destruction of the dental pulp may be almost entirely obviated by the application of a little chloroform on a pellet of cotton before the "nerve-paste" is applied, allowing it to remain a few seconds, and immediately stopping, thus preventing a rapid evaporation.

—The death of Dr. J. Collis Browne is announced from London. He formerly belonged to the medical staff of the British Army, and devised the well-known preparation "chlorodyne," for the cure of diarrhœa and similar diseases prevalent in the tropical possessions of England. Although the remedy was largely imitated and counterfeited, it is said to have secured great wealth for its inventor.

—Dr. Koch was born in 1843, and, when twenty-three years of age graduated, in Germany, as a doctor of medicine. For some six years he labored as an assistant in an obscure hospital, and in 1872 got an appointment at Wollstein, where he continued for seven years. His first marked step upward was gained by the publication of methods for coloring miscroscopic slides, and more particularly those of bacteria. Since then he has been principally engaged in those researches which have made him famous.

THE DESTRUCTIVE EFFECTS OF ALCOHOL.

BY JAS. L. PERRYMAN, A. M., M. D.,

Of Belleville, Illinois.

Opinionum commenta delet dies naturæ judicia confirmat.—*Cic.*

Time obliterates the fictions of opinion and confirms the decisions of nature.

Said the Right Hon. W. E. Gladstone, Prime Minister of England: "The evils of intemperance in the United Kingdom are equal to the combined calamities of war, pestilence, and famine, and this is the measure of our discredit and disgrace:"

It is a fact well known that alcohol is a product of fermentation of substances containing carbon, which is abundantly found in sugar and starch, and exists nowhere in the world as a natural product. It is the result, then, of a slow and destructive distillation of the natural chemical products of the vegetable world, and not until that fungus called yeast has produced death and decay is alcohol formed.

Thus it will be seen that alcohol is a chemical combination of carbon, hydrogen, and oxygen, discovered and made by art.

"Nature," says Count Chaptel, "never forms spirituous liquors. She rots the grape upon the branch, but it is art which converts the juice into wine; no chemist has ever yet found it among the substances formed by plants."

This statement is corroborated by the ablest physicians and chemists everywhere, and we shall try to show in the course of this article, to some extent at least, that alcohol, being an unnatural product, cannot be a nourishment, nor is it a life-giving or a life-sustaining element or substance. We are well aware of the fact, however, that there are some unsolved problems connected with its *modus operandi* upon the human body, and prejudice in its favor by mankind that must be overcome; but enough is known in reference to its baneful influence upon the animal economy to arraign it before a court of justice and at the bar of public opinion. The evidence that has accumulated by the statistics of the vital statistician and chemist, history and tradition warrant us in stating at the very outset of the investigation that the verdict of condemnation against the use of this fell destroyer and public enemy of the human race is not too severe; but in the course of the investigation we shall try, in our humble way, to give it and its advocates a fair and impartial hearing, for it is a principle of equity and justice that nothing should be condemned as pernicious and hurtful until an investigation has been obtained. And we shall assert, without the fear of contradiction or refutation, that alcohol is no more the gift of a beneficent Creator than small-pox, yellow fever, diphtheria, measles, typhus, typhoid, leprosy, or any other contagious or infectious disease.

I am well aware of the fact that not many years ago Baron Leibig, the distinguished German chemist, made the startling declaration that no alcohol left the animal economy unchanged, and that it greatly assisted combustion in the production of animal heat in combining with oxygen and passing out of the system as carbonic acid and water. A theory from so distinguished a scientist and chemist satisfied many and silenced

others; but it was a theory only, and, like all theories of the kind, it was soon doomed by more careful investigation of science to the shades of oblivion, which we shall presently show.

One fact that we all know and are familiar with, is that alcohol passes off by the breath, in fact, by all the excretions or emunctories of the body. Says Dr. James Kirk, of Scotland: "I dissected a man who died in a state of intoxication, after a debauch. The operation was performed a few hours after death. In two of the cavities of the brain—the lateral ventricles—was found the usual quantity of limpid fluid. When we smelled it the odor of whiskey was distinctly perceptible, and when we applied the candle to a portion in a spoon, it actually burned, the lambent blue flame characteristic of alcohol playing on the spoon for some seconds." Dr. Ogdon, of Aberdeen, corroborates the statement of Dr. Kirk. He says: "I am happy to be able to add one case to the number. The body of a woman, aged forty years, by the name of Callic, whom it was believed had drowned herself in a state of intoxication, was found on the 23d of August, 1831, in the Aberdeen canal. In company with another medical man, I was requested to examine the body. We discovered nearly four ounces of fluid in the ventricles, having all the physical qualities of alcohol, as was proved by the united testimony of two other medical men who saw the body and examined the fluids."

Three similar cases have occurred in the experience and practice of the writer. Three persons who had died after a drunken debauch. In company with several competent physicians and chemists, we discovered in the ventricles of the brain of two of the deceased upwards of two ounces and a half of fluid that had the odor of alcohol, and burned with a blue flame. Analysis by a competent chemist and a distinguished professor, demonstrated the presence of alcohol; in the ventricles of the other case it contained less than two ounces of fluid mingled with alcohol, which was proven by the tests applied.

These facts have been proven by experiments that have been made again and again by distinguished chemists and physicians upon the human body, and also upon the inferior animals. Chemistry has a tongue that is sharp and decisive. Like figures, it does not lie—for dogs, with other inferior animals, have been given alcohol until intoxication was produced—and from the blood alcohol was separated by chemical analysis and chemical reagents; it has been proven to be alcohol beyond the possibility of a doubt. *These facts go to establish not only a theory, but a fact*, that alcohol passes through the animal economy, unchanged, scorching, burning, disorganizing, paralyzing, and breaking down *sooner or later*, every tissue that it comes in contact with. Now I think that it can be clearly demonstrated by experiments and by post-mortem examinations, that alcohol produces death by its specific action upon the nervous centres, and not by coagulating the blood, as was asserted by Orphila and others; but in this age of light, lightning, steam, and gold, the exacting genius of this scientific and progressive age demands that everything pertaining to science must be demonstrated. "That which we know is little, but that which we know not is immense," exclaimed Laplace; a truism that we should keep in our mind's eye. It was also asserted and believed by Bouchardot and Sanders, that alcohol disappeared in combustion and respiration, that once formed carbonic acid and water, from its chemical affinity for water. These observers readily concluded that alcohol had been changed in its transit through the lungs, and that the carbonic acid gas produced death by asphyxia.

It has further been asserted by astute and learned chemists that a variety of chemical combinations have been formed from the presence of alcohol in the circulation, and that it was finally disposed of and thrown out of the system as carbonic acid and water—an assertion that is not borne out by the conclusions reached by the ablest chemists of both Europe and America.

It may be stated here, once for all, that recent scientific deductions based upon actual experiments with alcohol upon living animals, and by a post-mortem examination, the Leibigian theory of alcohol being a food was premature, and this unfortunate theory has been the author of as much drunkenness and debauchery, if not more, than any theory that was ever promulgated by any scientific physician and chemist, for it is now known that alcohol is not a food, it is not a medicine, nor is it a stimulant; neither does it prevent tissue change; neither does it produce any warmth of the body; but it is an anæsthetic—a narcotic poison which depresses and paralyzes the vital forces.

Dr. John Higginsbotham, of Nottingham, England, says that *is neither food nor physic.*

Let us suppose Leibig's theory is true—that alcohol is oxydized in the body—what will be the result? "The alcohol having a greater affinity for oxygen than for other elements of food, the hydrogen in the alcohol will unite with the free

oxygen circulating in the blood, and life is burned out too fast." Let us admit further for the sake of argument, that his theory is true. It would be a very costly nourishment, indeed, to say nothing of the quantity. It would require 2,920 quarts of the best Bavarian beer, which is equal to 116 quarts of pure alcohol, valued at $292, in order to obtain the nourishment that is in a five-pound loaf of bread, that will cost only thirty cents; and here it may be affirmed, without fear from the microscopic eye of chemical criticism, that no chemical of whatever name or nature, whether fluid or solid, animal or vegetable, taken into the system for the purpose of nourishment, can become a food unless it can be decomposed and oxydized in the lungs, blood, and tissues. The vito-chemical apparatus of the animal economy being unable to decompose alcohol, brandy, wine, and beer, the whole alcoholic family maintaining their chemical *union and integrity during their passage through the system unchanged, must exclude them as nourishment*, and for the same reason they should be excluded as medicine, which we shall prove by and by.

Dr. Gordon said: "It would be hard to find a more destructive poison than ardent spirits."

To recall that typical experiment of Dr. Percy, who injected two ounces of alcohol into the stomach of a dog, to use the doctor's own beautiful language, "Never did I see every spark of vitality more instantaneously extinguished." Death here must have been instantaneous—like that produced by prussic acid—by a shock to the whole nervous system.

The experiment of Lallemand, Perrin, and Duroy, forever exploded the food theory of Leibig, and on chemical grounds; for they demonstrated beyond a doubt that alcohol left the system as it entered it, a hydro-carbon unchanged, and "no one." says this triumvirate of genius and learning, "has yet found traces of any chemical resolution or combination;" and this statement is corroborated by Drs. Carpenter and Richardson, of England. Hence, says Dr. Hargraves, "Alcohol not being decomposed or oxidized in the system, it can neither generate heat, nor by assimilation become part of the tissues, and therefore can no more sustain vitality or produce force than the whip or spur can supply the place of oats, corn, and hay, and sustain the vitality or strength of a jaded nag." Referring again to the rapidity with which alcohol produces death, the writer has seen two persons die within a few minutes from an overdose of whiskey, one a well-to-do citizen, whom I shall never forget, who died wondering at the suddenness of his demise.

This makes us think of that terse, sharp, and truthful saying of Dr. Grindrod, who said: "A copious London beer drinker is all one vital spark—he wears his heart upon his sleeve, bare to a death wound from the claw of a cat or a rusty nail. Every medical man in London dreads a beer drinker for a patient in a surgical case." Dr. Gordon also says: "Among the coal-heavers who are brought to the London hospital, the mortality is frightful. Now, there is not a medical man in the kingdom of Great Britain, France, or the United States, of any respectability as a scholar in his profession, that would not corroborate the statement made by Drs. Grindrod and Gordon, of London.

If alcohol, wine, and beer could be acted upon by the system, as it acts upon sugar, starch, and fat, which is oxidized, partially burned off in the lungs, and partially in the system, leaving behind them their derivatives, carbonic acid and water; then it would be a nourishment, and the Leibigian theory would be true. But such is not the case, and the Leibigian theory, therefore, is false. Hence, I am not surprised at Dr. W. C. Carpenter, of London, who says alcohol cannot supply anything which is essential to the nutrition of the tissues. The reason for this is plain: it is not dissolved in the system, but it coagulates the blood, hardens the tissues, and coagulates albuminous substances, produces premature death in the blood-discs or corpuscles, robs them of their hematine, and is at war with every chemical tissue of nature, absorbing water from the tissues—for it is a great drinker itself—it is not a food, nor a *solvent* of food, nor can it in any way assist, directly or indirectly, in the building up of any tissue; nor can it prevent tissue change, the last ditch into which its friends and advocates have been driven, for it has been asserted by them that it prevents tissue change, which is not true. I am certain, after thirty years of experience in the practice of medicine and surgery, and close observation in reference to alcoholic stimulants in health and disease, that they are not necessary to sustain the vital forces, but on the contrary hurtful and positively injurious.

—The population of Japan, according to the census of 1883, amounts to 37,011,964; and at the end of the year 1883, the three largest towns contained the following number of inhabitants: Tokio, 299,191 families with 999,623 souls; Kioto, 203,477 families with 840,943 souls; and Osaka, 364,254 families with 1,585,696 souls.

UTERINE AND OVARIAN REFLEXES.

BY A. E. CALKINS, M, D.,
Of Bath, Clinton county, Mich.

(*Concluded from page* 314.)

The most common seat of all reflexes, originating both in the uterus and ovary, is through the solar plexus to the stomach, constituting a secondary indigestion or dyspepsia. A recent case of mine was as follows:

Mrs. B——, aged 37, small, weak, and anæmic, the mother of three children, the last born in March, 1884. Had a hard labor, and menorrhagia and leucorrhœa since, with frequent attacks of facial and intercostal neuralgia and nervous chills. Complains the most of pains at pit of stomach, accompanied with nausea and vomiting whenever food is taken. Bowels either costive or loose, seldom regular. Patient also troubled with palpitation of the heart and flushing of the face. Tongue clean and normal. Has formerly been treated with acids and alkalies, digestants of all kinds, hydrocyanic acid, nux vomica, etc., etc., with no favorable results. Physical examination revealed endometritis, which being treated, nervous communication lessened between stomach and cervix, and nutrition improved, resulted in a rapid and, so far, permanent recovery.

All reflex dyspepsias have a similar history, simulating closely in symptomatology, primary indigestion, so far as the stomach symptoms are concerned, but added to them, the neuralgias, hysterias, palpitations, and leucorrhœas of pelvic origin.

It is this same reflex dyspepsia that causes so much trouble in diagnosing and treating it. The cutting off of the gastric and intestinal juices causes fermentation of the food, which forms new foci of irritation in the solar plexus, and makes almost a primary disease from one that was originally entirely sympathetic. New symptoms are developed, dependent more upon the later points of irritation than upon the original cause. An intolerable vertex headache, accompanied with a sensation of swimming of the head and dizziness, are an almost pathognomonic evidence of cerebral anæmia, of brain starvation. The stomach not being competent to digest the food, the blood first shows the want of nutrition, becoming thin and pale; there is a venous hum in the neck, an aortic murmur, with palpitation and irregular heart action, showing muscular weakness as a secondary result of non-assimilation. The intellect becomes weakened from the same cause, and also from poisonous half-digested food.

The kidneys are influenced to some extent from the irritation sent up through the sympathetic to the renal plexus. Their blood-vessels are contracted, and the watery portion of the urine is lessened, while the specific gravity is increased. At the same time the uterine and vesical centres are in such close proximity in the lumbar region that more or less irritation is reflected to the walls of the bladder itself, producing what is known as the "irritable bladder."

The same is true of the rectum and sigmoid flexure, and this reflex stimulation may result in a corresponding diarrhœa.

Irritation may thus extend from the periphery of the nerves in the uterus and ovaries, along the sensory nerves, to vaso-motor centres in the organs affected, and there set up new foci of irritation producing the irritable stomach, heart, kidney, etc., or it may be reflected back to the immediate vicinity of the original irritation over the vaso-motor nerves and produce a form of transient hyperæmia, which in a healthy organism and from natural causes is perfectly innocent, but in a uterus or ovary morbidly sensitive, deformed or diseased, produces a condition far from innocuous.

With the organs of generation in a healthy state, the physiological rise and fall of blood pressure, representing the menstrual cycle; the transient congestion and engorgement characterizing the sexual act; the determination of blood to the part and hemorrhage in menstruation; the development of all the latent possibilities of the uterus, with subsidence of ovarian activity during gestation; and, finally, the gradual extinction of all the functions of propagation at the menopause; all of these acts are taking place for thirty years without in any way being injurious to the general well-being of the organism.

Capable as the uterus and ovaries are of filling their offices in a normal manner, yet it is the system most of all others liable to outside derangements, which acting in a circle tend to propagate and perpetuate mischief. An over-sensitive ovary, resulting from reflex irritation, as sexual excitement or excess, suddenly stands forth as a prominent cause of reflex disturbance in distant organs. There is pain over the ovary and extending down the leg, contracted muscles, with a marked degree of nausea, vomiting, flatulence, pain under the left breast and at the top of the head, and, above all, hysteria.

In primary flexions of the uterus, at first the only symptoms excepting sterility, are these distant reflex manifestations of nausea, palpitations, etc. The digestion is deranged, the amount of

food assimilated is insufficient to nourish the body, there is a gradually increasing want of nourishment, associated with feeble health ; the uterine tissues are starved, lose their firmness and tone, and the deformity increases with increasing results.

The same cycle of cause and effect, perpetuating each other, is illustrated in all hyperæmias and inflammations of the uterus and its appendages.

It is the management of uterine reflexes that proves the physician, and to a large degree founds his success financially. The treatment of pelvic reflexes may be studied under the three principal conditions producing them, viz. :

1. Social exciting causes.
2. Acquired mal-nutrition.
3. Hereditary susceptibility.

Whenever the exciting causes are prominent, and depend upon any mechanical or physical condition of the generative organs themselves, and can thus be satisfactorily diagnosed by examination and history, the cardinal indication is to remove the cause as far as possible. If it depends upon any abnormal position, with the organs still movable, replace and retain them in position by mechanical means of support. The simple act of replacement of a freshly-prolapsed uterus or strangulated ovary will instantaneously relieve all the urgent reflex symptoms. So also will sticking together the lips of a recently lacerated cervix or perineum ; while often scarification will more tardily relieve her sympathetic distress arising from subinvolution and endometritis. The continued injection of hot water has an important therapeutic action in producing softening and absorption of more chronic conditions of the uterus and peritoneum, while counter-irritation does the same work for a congested and tender ovary.

In many cases slight and seemingly trivial lesions must be followed to their origin before the key to the problem of cure is discovered. Thus, leucorrhœa is a very common companion of these reflexes, and a symptom which in itself may be caused by numerous and altogether opposite causes. We must go "back of the returns" in these cases, and remedy the first and "only cause" before we can hope for permanent relief.

Cases frequently occur in practice when sound judgment and keen discrimination must be used to determine whether to endeavor first to remove the cause, or whether to treat some of its reflex results, and in some cases the latter course is the only one left to the physician. These cases are mostly chronic ones, and in which long-continued irritation has produced new points or foci of disturbance, more important to be remedied than the original ones. Thus, when an irritable stomach is produced, which is utterly incapable of retaining a morsel of food, and exhaustion is imminent, a change of front is necessary, for nutrition must be maintained at all hazards. Then the indication for treatment is to lessen communication between the two irritated ganglia, and this is met by deadening the sensibility, and lessening the conductility of the sympathetic nerves. For this effect some combination of the narcotic stimulants are of great service, and especially the bromide of potassium. Whenever the stomach is so sensitive as to reject all medicines, it may be soothed by hypodermic injections of sulphate of morphia and a little ergotine to reduce the capillary congestion. Then the bromide may be administered by the mouth and retained, and the digestive powers of the stomach husbanded for a short time by injections per rectum of "beef peptonoids," etc. As soon as the intestinal tract has become able to furnish proper nourishment for the system, the uterus and ovaries should receive the whole attention of the medical attendant, and any displacement or disease appropriately treated. One method, right here, of common treatment I wish to write decidedly against, and that is the continued use of bromide of potash in cases of uterine reflexes. The only place it can occupy as a remedial agent is fully filled when the irritability of the stomach and other organs affected reflexly is overcome. Its long use proves so depressing to the nervous system as directly to aggravate its susceptibilities to reflex disturbances, for it is a well known law of physiology, that the more debilitated and ill-nourished an organ is, the more liable it is to irritations, and especially is this true of all viscera supplied by the sympathetic system. Tonics are the physicians' lever to move the world in these cases, after the organs have been restored to their normal functions as far as possible by removal of the local cause. Nux vomica with iron is the drug most powerful for good in my hands. It creates red blood, tones up and gives healthy tension to the nerve fibres, and every way acts as a special and general revivifier of no low order.

In regard to the management of cases of reflex manifestations in which no local lesion can be discovered, and in which no appreciable one is supposed to exist, little need be said. If it be a case with the tendency to reflexes inherited, the only treatment at present justifiable by our knowledge of pathology, is the judicious use of alteratives and tonics. A combination of iodide of

potassium and iron, with a liberal and digestible diet is of great value.

It is in the cases arising from acquired conditions of weakness, general and local, that our therapeutic armamentarium is of the most practical value. Here the indication is to meet and remedy a state of inactivity in the organs of digestion and assimilation. Poor food, poorly digested and imperfectly assimilated, has resulted in starvation to the tissues and nerve centres. To combat this state of affairs, commands careful attention to the diet, alimentary canal, and the perfect performance of the functions of that great blood-producer and renewer, the liver.

REFLECTIONS AND SKETCHES OF TOWN AND COUNTRY PRACTICE.—NO. 2.

BY GEORGE HILL, M. D.,
Of Hughesville, Pa.

"*I have taken much pains to learn how ignorant the graduates of the last twenty years are in relation to the art of bleeding, and find that they do not know how to do it.*"—Dr. Hiram Corson, July 15, 1884.

Only last week I was called in consultation with Dr. X., a young physician of large practice. In the case, venesection was decided the thing to do. The doctor tied a pocket-handkerchief loosely around the arm of the patient, and was about to use a stick *a la tourniquet!*—when I asked the privilege, in lieu thereof, of simply throwing a strip of muslin an inch and a half wide and a yard and a quarter long, twice around the arm, and archly remarking at the same time, that in *this case* it would only be necessary to *dam* the superficial veins. But when to my horror he was about to plunge the lancet directly at right angles to the vein, and regardless of the prominent tendon of the biceps and the pulsating brachial artery, a second halt in the proceedings was called.

The doctor told me afterwards that bleeding had been somewhat of a failure with him—as in a previous effort, he had actually cut the artery, "*but no harm had come of it!*" And further, in excuse for himself, he said that venesection had not been regularly taught during his medical course of study, but only briefly alluded to occasionally, D. H., of this place, who has been in practice three years, says he has never bled any one, and only in one instance in his life, witnessed the procedure. He is now very anxious to know *how* and *when* to bleed, which is certainly a most commendable ambition. He declares that he heard little or nothing during his entire medical course on the subject of blood-letting. Hence, he said to me this morning in my office, "*I am afraid to bleed.*" Such testimony is so astounding, as well as humiliating, that I forbear giving anything further of this sort; hoping, but somewhat against hope, that these are exceptional cases.

On the second of the present month I was called in consultation with Doctor E——. Case, labor. First pregnancy; age 33. A plethoric and healthy woman, normal weight 150 pounds. Found head extra-uterine, scalp doughy and much tumefied, labia swollen, vaginal walls tender, rough, and dry, pains regular and very severe. Recommended copious bleeding previous to delivery perforce. Was antagonized—and reluctantly, am sorry to add culpably, yielded. As the case was imminent, proceeded at once to administer an anæsthetic; when the Doctor, after some difficulty, succeeded in locking his forceps, but failed in his efforts to deliver, he asked me to take his place, which I did, finding the difficulty mainly *suction* or atmospheric pressure, which is one of the serious drawbacks in perfect anæsthesia. Hence, without deft manipulation, and the admission of air by means of the free hand, the traction necessary for delivery is absolutely unwarrantable. Permit me here to *emphasize*, as I am not aware that this feature is dwelt upon by those who teach. For if a time ever occurs when the accoucheur may be specially liable to break, unwittingly, the Fifth Commandment, it is in the trying moments when the *delicate atlas* becomes the pivot of all his power. In two or three minutes the head was delivered, but the trunk remained until after consciousness returned; and then, two teaspoonfuls of fluid extract of ergot were required to produce expulsive force sufficient for extrusion. The child was resuscitated, and the placenta was readily removed. In a fraction beyond two days I was again called to this case. Found pulse 120, occasional delirium, bowels tympanitic, much tenderness throughout the hypogastrium. Vaginal walls as far as visible highly inflamed, no laceration, reported chills yesterday and day before. The doctor in charge at once proposed *blood-letting*, which I could only then sanction so far as to say that a little bleeding would do no harm, but was compelled to utter the *unwelcome fact* that the time for bleeding and the removal of that surplusage, that was now probably working death, was past. This woman should have been bled hours before her delivery, and what would have been better still, a blood-letting two or three weeks before her expected time, and such diet and treatment as would have special view to the excretions, especially the kid

neys and bowels. This second visit was on the 4th inst.; she died on the 9th. The student of natural science, whoever he may be, cannot fail to see the apparent *over-work and waste* in reproduction down through all of animal and vegetable life, and to this the astute physician will ever find the *highest type of animal life* no exception.

Some years ago the writer was called in consultation a distance of twelve miles; arrived at 6 p. m. Case puerperal convulsions; first pregnancy; age twenty; medium in stature; usual weight 110; always healthy. Commenced with the fits twelve hours before. Patient unconscious, and had been for several hours. Os but little dilated and very rigid; child alive. In consultation, found the attending physician a clever talker, but mounted on his hobby high—*never bleed!* And when I proposed that we make this case an exception, he met me with arguments which there was no time to antagonize in this emergency. And very soon I was forced to break in upon him by saying, "Bleed and deliver, and you may save your patient alive; without it, she *must die:* this is my ultimatum; if not carried out at once I am of no use, and shall retire." Not receiving his consent, the pow-wow ended.

As I was about to depart in disgust, the father, mother, and husband, approached me, and the father said: "*Doctor, if thee thinks bleeding necessary, and can do anything for us in our great distress, remain and do so.*" Humanity proved stronger than ethics. I bled freely, and soon her livid and swollen countenance became more placid and pale, and the convulsion greatly mitigated in violence. In the use of cold applications to the head and warm to the extremities, at the termination of about two hours the womb had yielded sufficiently to admit the blades of the forceps. Being comatose, she was delivered in the interval without an anæsthetic, in order to have the feeble expulsive efforts that yet remained.

Five days after delivery, I again saw this patient. She had then, for the first, become conscious that she was the mother of a living child. She said: "*Doctor, I hear thee, but I cannot see thee. Shall I ever see?*" I assured her that not only sight but health would be hers. In due time she recovered.

Permit me to add the incontrovertible truth, that by this bold venesection a premature and dual death was averted. It is a well-known principle that in all the acute inflammations the fibrin of the blood is no longer so readily held in solution, or, more correctly, suspension, and thus in passing through the morbid tissues, produces stasis and hypertrophy, or is dropped as inorganic deposit or coagula; and thus that which in health is life, in disease works ruin and death. Hence, it was the intention at the beginning of this article to explain why I am more apt to bleed than some of my neighbors in this class of cases. This design was not carried out in this article, but may possibly be in the future.

It cannot be disguised that the medical profession has been greatly dazzled by the immense advances in every branch of the science during the last thirty years. This may be a *reason*, but ought not to be, why that mighty lever of our *art*, venesection, should be cast aside, or even put on half duty.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. Seelye, A. M., M. D.

Pulmonary Abscess.

Patient is a woman 38 years of age, a native of Ireland, single, and a servant. She was admitted on the 13th of January. There is no rheumatic or phthisical family history. She had an attack of rheumatism fifteen years ago. Does not use stimulants, and has never had syphilis. Twelve days before her admission she had a chill, followed by fever, vomiting, pain in the left chest, and a feeling of prostration. But she kept about at her work, and only complained of shortness of breath, and a little cough, which was attended with a slight yellowish expectoration which did not contain any blood. She finally became so weak that she had to take to her bed. Her bowels have been regular, and micturition normal. On admission, her pulse was 98, respiration 28, and temperature 101°. Upon examination, patient's condition was fair; she was well nourished, and presented no œdema. Her treatment since her admission has been three to six ounces of brandy by day, and two to three ounces at night, with digitalis, spirit of mindererus, and carbonate of ammonia, and iodine has been painted over a portion of the left side of the chest. Last night she was seized with a violent fit of coughing, and she raised two cupfuls of gangrenous matter, with a foul and offensive odor. The odor of her breath was also very foul. At that time her pulse was 120, respiration 51, and temperature 101°. One ounce of brandy was ordered every hour, with 5 grains of ammonia carbonate and 13 of tincture of digitalis and spirit of mindererus.

Gentlemen, I find upon examination to-day very little expansive movement of the left chest, but the elevation movement is rather more satisfactory. I get no vocal fremitus either under the clavicle or at the side of the chest. Upon percussion of the left chest, I get no subclavicular dullness, and none till I come to the upper margin of the proper region of præcordial dullness. And outside of the region of præcordial dullness, I find

fair resonance as low down as the sixth rib. Below this I get dullness. Upon auscultation, I get a very good respiratory movement and murmur over the region of resonance, but at the fourth or fifth intercostal space I get very marked pleuritic friction-sounds. While she is sitting up I find that there is the same defective movement of the left side, which is almost still, while that of the right side is somewhat exaggerated. Posteriorly upon percussion I get a fair degree of resonance from above, down to a point about one inch below the inferior angle of the scapula on the left side. The vocal fremitus is not very clear, either above or below the line of dullness. I find very shallow breathing, but still vesicular breathing in the upper part of the left lung, and it seems so shallow because the lung moves very imperfectly. But at the line of dullness I begin to get bronchial respiration and bronchial voice, and upon forcible respiration I get a breathing sound, approaching to what is called cavernous breathing rather than bronchial.

You have heard the history, and you have seen the physical examination. It is now more than two weeks since she was taken ill with fever, pain in the left chest, and a cough. But note, she was not confined to her bed for several days, but kept about at her work. Now I have told you before that this is the history which we usually get here of pleurisy. It is not uncommon for such patients to come into the hospital, and then upon examination we find the chest more or less filled with fluid. The patient has, in fact, had pleurisy for some time, but he goes on with his work until he is obliged to give up because of the distress caused by the accumulation of the fluid in the chest, which interferes with the respiration. She came in last Friday, and from the physical examination there was some doubt whether the signs of dullness and loss of respiratory murmur indicated an inflammation of the lung itself, or only a simple pleurisy. To determine this the doctor punctured her chest with a hypodermic needle, but he failed to get any fluid; and so we came to the conclusion that we had to deal with a subacute pulmonic consolidation. There were some dry friction rales in the axillary portion of the lung, but there was no cough and no rusty characteristic pneumonic expectoration. But in furtherance of the idea that it was a consolidation of lung tissue rather than an effusion of fluid, was the fact that there was no displacement of the heart. Last evening she was seized with a sudden fit of coughing, and she began to expectorate very freely an extremely fetid mucoid expectoration, which nearly filled two ordinary cups. Now this might indicate one of two things: it might indicate that there had been a circumscribed empyema, which on account of its viscidity would not flow through the hypodermic needle, or else it was not reached by the needle. This formed an abscess which connected with the air by the bronchial tubes, and it continued to grow until it finally forced its way through the lung tissue into one of the larger bronchial tubes, and was thus discharged in a fit of coughing. Or this might be one of those cases of central gangrene of the lung which sometimes occur, and which are only brought to your attention by the usual signs of a subacute pneumonia.

I am inclined to think that the first hypothesis is not the correct one; because if a perforation of the lung had occurred so as to make a commuication between the bronchial tubes and the pleural cavity, there would have been a greater disturbance of the respiratory functions than there was here, and the perforation would have been indicated, probably, by the usual characteristic signs of perforation. For in the pneumothorax of perforation you get a very sudden and extreme agony of pain, with very great dyspnœa, as a rule, because there is a more or less complete collapse of the lung from the entrance of air into the pleural cavity. But there were no such signs here. You see she lies upon the sound side, and she therefore has enough of the left lung left to breathe comfortably while lying upon the right side. And the assuming of this posture is usually a sign that there is still a considerable amount of useful lung-tissue remaining in the diseased lung. For where one lung is obliged to do all the work, lying upon that side would impede its expansion, and thus increase the dyspnœa. So I think that we are led to the conclusion that we have to deal with a gangrene of the lung, together with a surrounding subacute pleuro-pneumonia. And the gangrene has probably spread by causing a softening of the tissues around it, until it finally perforated a large enough bronchial tube to allow the emptying into it of the contents of this gangrenous abscess. And this was what took place last evening, when she coughed up a very offensive expectoration. Her breath is even now offensive, and has a gangrenous odor. This disagreeable odor is one of the most characteristic features of this disease. The expectorations can be deodorized, but the foul breath is harder to manage.

Gangrene of the lung is not a very common affection, and the cause which gives rise to it is usually exposure; and, in fact, this is the only exciting cause that I know of. It is probable that what determines the gangrene is a localized apoplexy of the lung, or the formation of a thrombus in a branch of the bronchial arteries. The most frequent location for it is in the middle lobe of the right lung.

The prognosis of this disease is very unsettled. If the lesion is of small size it may heal up, and the patient may fully recover after a protracted illness. There is usually more or less pneumonia around the seat of the gangrenous disease, and the tendency is to the extension of this gangrenous cavity until it becomes so large that it finally gets beyond the capacity of repair. Under these circumstances it presents the features, and follows the usual course of phthisis. But you must not always suppose that because you get a gangrenous breath you have to deal with gangrene of the lungs. There is a peculiar odor to the breath in fetid bronchitis which is so like that in gangrene of the lung that you cannot distinguish any difference between them. But in such cases you have the signs of a more extensive bronchial affection than there are here. Here we have an acute history of a destructive process, resulting in the formation of an abscess which finally perforated through the lung into a bronchial tube, and an accompanying pleuro-pneumonia. Ultimate dissolution will probably be the end of this process.

Medical Societies.

PROCEEDINGS OF THE LOUISVILLE MEDICAL SOCIETY.

[Reported for the Medical and Surgical Reporter by Allen Kelch, M. D.]

The proceedings at the meeting of the Louisville Medical Society, July 31, were begun by the reading of a paper on

Umbilical Hemorrhage,

by Julia Ingram, M. D., who said:

"The subject of umbilical hemorrhage is one on which as yet the physician is much at sea. Its intractability and its generally fatal result render it a much dreaded as well as an interesting disease. In order to bring the subject before you, I shall report some cases which have come under my notice, and I hope from remarks elicited by my paper to gain instead of imparting information. The first case which I shall mention is recalled from memory. Labor slow; delivery instrumental. There was a slight abrasion made by the forceps on the inferior maxilla. During the ensuing night there was some hemorrhage from this abrasion and from the cord, which, according to the rule of the hospital, was not ligated. The hemorrhage ceased during the next day. The fourth and fifth days there was hemorrhage at the base of the cord, which was detached on the night of the fifth. The hemorrhage still continued from the umbilicus, and there was slight hemorrhage from the bowels. Compression, tannic acid, Monsel's solution, and needles, were successively used without material influence. The child died on the seventh day. No autopsy.

"While in charge of the Maternity Department of the New England Hospital, three cases occurred in unusually rapid succession.

"Case 1. A primipara, aged 25. Labor began 5 p. m., October 13, 1882; child expelled 7:45 p. m. A short, easy labor, no hemorrhage, child a male, weight 9 pounds, seemed strong and healthy. Nothing abnormal noticed until the morning of the third day, when a fluctuating tumor became perceptible on the posterior upper border of each parietal bone. October 17.—The tumors have increased in size. The larger one, that on the right, measures 11 cm. in the longer and 7 cm. in the shorter diameter. The mouth shows great congestion, especially at the back part of the hard palate, and the blood oozes from the surface in the act of sucking. Spots of extravasated blood are seen on the under part of the jaw and about the inner malleoli. October 18, the hemorrhage still continues. There is bleeding from the umbilicus, and blood in the evacuations.

℞. Tinct. ferri. chlor., 0.06.
Acid. sulph. (dil.), 0.12.
M. S. To be given every four hours.

"Tannic acid applied to the umbilicus having failed to stop the bleeding, ferri subsulphate is applied under a compress. The child still continues to eat when fed, but is not allowed to nurse on account of the pain and flow of blood from the buccal cavity. The bleeding from the bowels and umbilicus still continues. Faint lines of congestion are seen at the margin of the nails. A decided icteroid hue has appeared. October 19. Child died at 3 a. m. No post mortem.

"Case 2. Primipara, aged 17. Labor began October 13, 11 p. m.; child born October 14, 8:30 a. m. No hemorrhage. Child a male; weight eight pounds. October 15. Baby's left eye congested, and some pus. Treated with zinc sulph. $O.\frac{2.5}{3.0}$. October 17. The eye is still congested. The baby does not nurse well, and has little desire for food. October 18. Stump of cord separated to-day. October 24. There is slight bleeding at the umbilicus. Acid tannic was applied and compression used. October 25. There is still some bleeding. The application of yesterday is repeated. Baby nurses well; p. m., the bleeding continues; ext. ergotæ fld., 1.20 given per rectum. October 26. Dose of ergot repeated at midnight. It was not retained, and in one-half hour was again repeated. Another injection was given at 6 a. m. to be repeated every six hours. Compresses were changed at intervals of two hours during the night. They were saturated with blood. Spts. turpentine was applied to the umbilicus on absorbent cotton; compression is constantly kept up. There is a marked icteroid hue, October 27. The baby does not nurse well. Injections per rectum of milk and brandy are ordered to be given alternately every fifteen minutes. The finger is held on the umbilicus constantly to exert compression. October 28. Baby died this a. m. During the night it vomited blood four times, and during the morning three times. Nothing but brandy was retained by the by the bowels. October 29. *Post mortem*—Tissues and organs very anæmic. The heart of normal size, but the right ventricle very small. No septum between the auricles. Two stomachs were found, the first of normal size, the second smaller, but otherwise the exact counterpart of the larger. Both were filled with a dark liquid which appeared to be disorganized blood. The other organs were apparently normal.

"Case 3. Primipara, aged 25. Labor began October 22, 5 p. m. Child expelled October 23, 6 a. m. Labor normal. Hemorrhage not excessive. The child a male, unusually large and well developed; weight, ten pounds. The head greatly moulded. October 25. The child has a peculiar whining cry. The left side of the face is partially paralyzed. It nurses well. October 27. There is a slight umbilical hemorrhage and some redness at the base of the cord. The paralysis of the face is more marked. October 28. The stump of the cord detached. There is still some hemorrhage. October 29. Child has two convulsions during the night. The anterior fontanelle is slightly bulged. The hemorrhage from the umbilicus still continues. The child eats when fed. It is much blanched. October 30. Child died in convulsions this a. m. The hemorrhage continued up to death, in spite of compresses and styptics. No post mortem. So many cases occurring in so short a time, and in the same ward, gave rise to close and careful scrutiny of all surroundings and possible mechanical causes bearing upon them. Nothing could be discovered in the sanitary condition or nursing that could even indirectly influence such a result.

"One case of lacerated perineum operated on and placed in the same ward healed perfectly by

first intention, showing that there could scarcely be any very unfavorable sanitary condition.

"The mothers of these infants were primiparæ, and all made rapid recovery. They gave good family history. No trace of hemorrhagic diathesis could be found. Their condition during pregnancy was good. In two of the four cases icterus appeared after hemorrhage began. In one case there was rather obstinate constipation. In three cases the bleeding began before the complete detachment of the cord. In the one case of post mortem nothing abnormal was discovered about the liver. In no case was there any tendency to the formation of a clot. Some of the blood caught and exposed to the air showed no coagulum. These cases were all male infants.

"Hemorrhage from the umbilicus may occur either before or after the natural separation of the funis. If before, it usually arises from accidental or violent separation of the cord, or improper ligation. If it occur at the time or after the separation of the cord, it is more serious and in the majority of cases a fatal malady. Cases have been reported where, when the cord had separated, the blood-vessels had failed to close, and alarming and even fatal hemorrhage occurred. In others, the normal contractility of the vessels has been lost in consequence of some inflammatory condition. Again, abscesses may form here, which, on their discharge, are accompanied by blood. But far the greater proportion of these cases apparently depend upon some morbid condition of the blood itself, due to different causes. In some cases this impoverishment may be traced to syphilitic origin; in others to improper hygienic conditions during gestation. Yet it is not confined to puny infants. In these cases reported each was over average weight and size. In a number of cases which have been reported the mothers gave history of hemorrhagic diathesis, shown in menorrhagia, excessive loss of blood in parturition or on slight injury. Hereditary predisposition is quite marked in some cases. Mr. Ray reports a case which was the third male child of the same mother, who had died of hemorrhage from the umbilicus, and speaks of one where four male children of the same mother had died from this cause. Dr. Minot also mentions one case of a woman who had lost four children, and of another who lost two in the same way. Dr. Bowditch reports two cases of the same mother. The first a female; cord fell off the third day. Hemorrhage began on the fourteenth. Styptics, compresses, etc., were tried ineffectually, when hare-lip needles were used with temporary success. On the eighteenth day bleeding returned; on the nineteenth hemorrhage from the bowels, and on the twentieth death occurred. The mother, after being delivered of two children having no tendency to hemorrhage, gave birth to a male infant. The cord fell off on the fifth day, and on the tenth hemorrhage began. The child died on the fourteenth day, in spite of all means, the cautery included. Jaundice occurred during life, and the liver was found much diseased in this case. The character of the labor apparently has no bearing upon this condition. Short and easy labors are as prone to usher in a hemorrhagic infant as a long and difficult one. Jaundice is one cause given for this hemorrhagic condition. It is claimed that, whether due to malformation of the liver or icterus neonatorum, it results in an impoverishment of the blood, and diminishes coagulability. Dr. Minot mentions that in three or four out of seven cases the liver presented deviations from the ordinarily healthy appearance. Organic disease of the liver has not been found in the majority of cases, and these deviations spoken of by Dr. Minot may be secondary. In the cases where icterus has occurred, it is not found oftenest to precede, but to follow hemorrhage. May the discoloration of the skin be, at least in many cases, hæmatogenous, and this diminished coagulability be due to other causes than a morbid condition of the liver? I know of no treatment that is relied upon for any good permanent result. Compresses of various materials, styptics, needles, and the actual cautery, have been used with temporary relief, but with exceptionally permanent success.

"Theoretically, constitutional treatment of the mother during the period of gestation would afford best results; but this would apply only to cases of hemorrhagic history, and I know of no reports of supposed success in such cases."

DISCUSSION.

Dr. Frank Wilson had met with but one case of umbilical hemorrhage, and this, as usually happens, was fatal. He had frequently seen oozing of blood from the umbilicus after the cord had had dropped off, but this had usually ceased by the application of the simpler means for controlling hemorrhage. In the fatal case use was made of most of the means suggested in the paper just read. In fact, they comprise about all we can make use of in a medical sense. Beyond those mentioned, surgical procedures it appears to me might be resorted to by cutting down upon the cord and re-ligating.

Dr. Edward von Donhoff said: "I intended to say nothing upon this subject until Dr. Wilson's suggestion concerning the surgical aspects of these cases reminds me of an experience which I published within the time of Dr. Gailliard's residence in this city. I saw a case in consulation in the person of a boy three days old. The cord was apparently diseased, and from the base of it considerable blood had been oozing since its birth. The means as suggested in the paper having been used, I suggested the propriety of putting a ligature on the cord submurally. For the purpose of doing this I passed a short needle down around the cord, and endeavored to bring it out at the same opening as far as possible. In this I succeeded to that extent that the boy is still living, and is now some ten or twelve years old.

"This subject was discussed at the medico-chirurgical society, and the conclusions arrived at were that this cause of infantile fatality is largely associated with mechanical derangements of the cord, and often enough, though it is not possible to discover clearly syphilitic history, yet it is possible frequently enough to justify the inference that this constitutional infection is largely causative.

"I do not think that structural defectiveness is determinable without dissection of the cord. In the case to which I have referred, the bleeding was general throughout the entire length of the

cord, and when a piece of it was removed after applying this second ligature its structure presented a soft, loose, spongy appearance. To say that these cases are associated with the hemorrhagic diathesis, however, letting the matter rest there, is saying little or nothing. To constitute the hemorrhagic diathesis there must be a mal-organization of structure, and at the same time defective blood properties. There is defect of fibrin or of the albuminoids in the blood, as was apparent in one of the cases reported. The hemorrhage is but a factor even in the hemorrhagic diathesis, and the trouble against which it would appear impossible to do anything is the structural defectiveness. In the case which I reported, if that factor had been present the ligature would probably have amounted to nothing. I have no doubt that most instances are associated with immaturity at birth, although the cord may appear to be perfectly healthy, and yet be unfitted for the collapsing process which in the normal condition of things takes place readily.

"Syphilis is so fruitful of everything that can militate against the life of the child, that it is certainly important to notice the history and the evidences of its inheritance. In the case I have referred to, the child was the offspring of a mulatto woman and a white father, and presented an appearance such as might be expected of a child of such parentage, yet it was by no means cadaveric. Since that time the child has exhibited signs of inherited syphilis."

Dr. J. H. O'Reiley said: "The reader of the paper has so thoroughly canvassed the subject with reference to the causation and mechanical measures to be adopted for the relief of this condition, that but little remains to be said, and that only in a general way upon the subject. Most of these cases reported struck me as being clearly of that diathesis known as the hemorrhagic.

"I have not infrequently seen umbilical hemorrhage occur from loosening or slipping of ligature, and I have occasionally brought it about purposely to relieve congestion. I have never had, however, a case of hemorrhagic diathesis in this connection to deal with. In these cases reported the father's condition has not been ascertained. There may have been syphilis at the bottom of the blood dyscrasia.

"It occurs to me that there can be no better field for the application of the principles of prophylaxis than is presented in these very cases."

Dr. Leber thought it a matter of importance to consider the source of hemorrhage in these cases. Shortly after birth it is most likely to have as its source the hypogastric arteries, and later, the umbilical vein, and again it may occur from the capillaries extending with cord into the abdomen. In these cases bleeding is never violent, but constant oozing takes place. Of this variety I have never seen but two cases, both of which proved fatal. If the hemorrhage is due to traumatism then you may succeed in arresting it by religating. I believe that in every case some diathesis underlies this process. Icterus sometimes precedes, sometimes follows the hemorrhage. It is evidently due to some faulty condition of the blood or to some diseased condition of the walls.

Dr. Preston Scott said: "There is much that is accidental; something of good and bad luck in medicine. For instance, one speaker has referred to his rare observation of placenta previa. In an experience of over twenty-five years it has been my good fortune not to have had one case. Nearly so in regard to the subject before the meeting. Only one time has the accident, umbilical hemorrhage, occurred to me. That is now so long since I can only recall that the subject was icteroid, and the event fatal despite styptics and the ligature. There must be some dyscrasia or some congenital deficiency to favor this accident. Were struma, or syphilis, or jaundice, the predisposing conditions, I have had ample opportunity to observe the event. That the question of tying or not tying the cord, or the manner of tying, has but little bearing on this event, is seen in the fact that it occurs as infrequently in the skilled and unskilled.

"The experience of the leader of this discussion is assuredly a rare one. The report is interesting in its accuracy and authenticity. It is to be noted that, with one exception, there is no appearance of any constitutional state, hereditary or otherwise, to account for the event.

"In illustration of the rarity of the occurrence, the Vienna Foundling Asylum reports thirteen cases in fifty thousand. Vogel reports only one case in ten thousand children."

Dr. Dudley S. Reynolds said: "I have been much impressed by the reading and discussion of this paper. It opens up a very important question in this connection, and that is the question of development, as well as the question of the classification already suggested in the discussion. One kind of hemorrhage comes on in undeveloped creatures as a result of structural deficiency. This is the class to which belonged the case cited in the paper as having hemorrhages from the buccal mucous membrane, the abrasions wherever occurring on the body; the tumors about the funis from which the blood oozed away, and that general condition characteristic of undeveloped, incomplete structural organization.

"In the case reported by Dr. Donhoff, it is quite certain that that structural deficiency did not exist.

"Hemorrhage may be due to mechanical injury, it may be due to sudden and severe contraction of the abdominal muscles of the child, but those are entirely different things from that hemorrhage which is due to mal-nutrition of the mother.

"A long time ago the hemorrhagic diathesis was an interesting problem to me for study. It was equally interesting with the study of that other great problem of 'taking cold,' or 'diseased or disordered liver,' and kindred mysterious subjects. Thus I arrived at the conclusion that the hemorrhagic diathesis means simply incomplete or imperfect form or structure of the vessels or tissues in which they ramify. It is not proper to ascribe this condition to syphilis unless other evidences of that disease are present. Syphilis is a disease which, whether acquired or inherited, has distinctly marked characteristics in very many of its stages, and it ought to be discerned and is recognized by astute practitioners of medicine by these characteristics.

"As to the cases detailed, these children were most likely the illegitimate offspring of people in

indigent circumstances. So, too, a vast majority of cases will be found to occur among the unfortunate classes of people. From these classes came the mothers who give birth to children who die of umbilical hemorrhage.

"The question then, it appears to me, resolves itself into this conclusion, viz., umbilical hemorrhage purely local in character, can and ought to be controlled; but when associated with general hemorrhages are fatal by virtue of necessity, on account of imperfect development, and are beyond the reach of medical agents."

EDITORIAL DEPARTMENT.

PERISCOPE.

Lister's Antiseptic Treatment.

In the absence of Sir Joseph Lister, Professor Esmarch (Kiel) opened a discussion on this subject at the late meeting of the International Medical Congress. He began by expressing his regret at the absence of the illustrious master and teacher of them all; and then described the plan of treatment followed in his own hospital practice. The aim was the avoidance of suppuration, and the leaving of the wound undisturbed. This was best done by a permanent dressing, preventing the entrance of germs. The things required were: 1, exact hæmostasis; 2, the avoidance of cavities in the interior of the wounds; 3, drainage, artificial ischæmia, the application of numerous catgut ligatures on large and small vessels, and the application of a bandage before the removal of the tourniquet, support of all the deep parts by pressure, turning in of the edges of the skin, and pressure. Drainage-tubes, as preventing healing, were not now used by him, but openings were left for the escape of exudations. Asepsis was minutely studied. The bandages were sterilized by dry heat and corrosive sublimate. The spray was used only before operating, so as to disinfect the air in the room. In one operation, distilled water with salt, of the specific gravity of the blood, was used for irrigation, but at the end corrosive sublimate was employed. Other antiseptics, as iodoform, were occasionally used. For bandages, loose absorbent soft matter was needed. Peat was used in pillows (without macintosh) dipped in carbolic lotion. The parts were rendered immovable by glass splints till healing by the first intention was obtained. This occurred in from 4, 8, 10, or 14 days, to 5 or 6 weeks, after operation.

Dr. Mosetig-Moorhof (Vienna) advocated the iodoform treatment of wounds, and said that he used no other antiseptic. Hs used cold water during operations. There was no irritation, and asepsis was certain. Iodoform prevented transudation of the white blood-cells. He narrated a case of traumatic septic gangrene extending above the knee, where yet the knee-joint was found aseptic at the *post mortem* examination. Iodoform also diminished pain.

Dr. Schede (Hamburg) said that the principles of antiseptic treatment remained unaltered, though the methods had changed. After his training in Halle, when called to Berlin, he found Lister's method perfect in its results. But in Hamburg he never had perfect success with Listerism; he was now unable quite to exclude accidental wound-disease from his cases. The hospital was old, and in many respects undesirably arranged and situated. He tried iodoform with good results. He had also tried corrosive sublimate, and, after experience, had got from it brilliant results. Erysipelas at once disappeared; not one case had occurred under the sublimate dressing in his wards; no septicæmia, no pyæmia, no irritation. He used it in the proportion of 1 to 500, and had had no case of poisoning. Sometimes, however, there was tenesmus of the rectum. Children especially tolerated the sublimate well. In the dressings, he tried to keep everything dry.

Dr. Mikuliez (Cracow) did not agree with either Dr. Mosetig-Moorhof or Dr. Schede. In his hospital, which was much worse than Dr. Schede's, he had had no erysipelas with iodoform; but iodoform could not be used alone. Other soluble substances must be used, where its insolubility prevented it from fulfilling the indications. He disinfected with solution of carbolic acid, or of corrosive sublimate, and used no spray; in the vagina he plugged the canal with iodoform gauze; in the rectum he stitched one side and the upper end of the sphincter, and used no drain, even when the peritoneum was opened. Poisoning occurred only from excessive use.

Dr. Neudorfer (Vienna) said the aims of antiseptic surgery were the same, but the methods varied, and must vary, very greatly. Each surgeon was satisfied with his own plan, and really got good results; but statistics were not of much value. Surgeons must study rather in the direction of sepsis. Sepsis required water; therefore he used no water in his treatment of wounds. He used no sponges, but a dry towel crumpled together, to wipe up the blood. The serum of the blood should be studied; oxidation and deoxidation were important processes. He used for wounds peroxide of hydrogen, and had found singularly good results.

Professor Buchanan (Glasgow) said that the discussion of antiseptics without Lister was like the play of *Hamlet* with the Prince of Denmark left out. As a representative of Scotland, the home of antiseptic surgery, a colleague of Lister, and one who had witnessed his earliest results, he wished to contribute a few words to the discussion. He agreed that the principles of antisepsis were the same, though the methods might vary; and he described the method now employed in Glasgow.

Mr. Schelkley (America) said that the tendency to sepsis, etc., was different in different cases. His practice was in the tropics. At first he used thorough Listerism; he nev··, however, got heal-

ing by the first intention, but always slight sloughing of the surface, and union by the second intention; yet there was no pus nor any pain. He then changed the plan, ceased to use the spray, and irrigated during the operation with salicylic acid or corrosive sublimate, and used iodoform dressing or boracic lint. Salicylic acid and iodoform gave the best results, yet he did not get union by the first intention.

Dr. Koeberle (Strassburg) said that for some time he had used only linen to wipe wounds, and had since had no erysipelas among his operations. He claimed to have had better results than Schede; even his ovariotomies were all cured.

Professor Plum (Copenhagen) said that the Danish surgeons agreed entirely with Germany, but he could not support Esmarch's plan, on account of the cost. The chief antiseptics were soap and brush, and by simple means much might be done.

Dr. Trélat (Paris) said that he had three years ago laid down the following rules: The wound should be made of a form suitable for healing by first intention, and perfectly adapted. No foreign body, either mechanical or septic, should be left in the wound. Antiseptics did not exist in some countries—not on the top of Chimborazo; and half educated Americans did remarkable operations on negroes. The principles of antiseptics were not altered; the practice was being perfected. He used iodoform gauze, chiefly as plugs, and superficially as required. He applied a large cushion, pressed with elastic bandages, to the wound, changing the dressings on the fifteenth day.

Dr. Mosetig-Moorhof challenged Dr. Milkuliez to say that he had ever tried a thorough iodoform dressing; and, if not, how could he know that iodoform required other antiseptics to supplement its use. At the same time, when Dr. Schede tried iodoform, there was an epidemic of erysipelas all over Europe; and if he would try it now, he would get better results.

Professor Plum closed the debate with a compliment to Sir Joseph Lister, which was received with great applause.

Muscular Wasting Co-existent with Joint Disease.

Dr. William M. Ord, in his address in medicine, before the Brit. Med. Ass. at its last meeting, said:

For some years I have been led to observe, in a certain group of cases of chronic rheumatic arthritis, the co-existence with the joint-lesion, always well marked, of affections of muscles. These have been not merely weakness of extensors, and tonic contraction of flexors, the two factors which largely determine the character of the deformities of the disease, but marked and excessive wasting of muscles, closely resembling those of progressive muscular atrophy. Together with these, I have noted the existence of fibrillar tremors, and of electrical reactions like those of progressive muscular atrophy in the general, but with some indications of less loss of galvanic than of Faradic sensibility, with some slight indication of the reaction of degeneration.

In addition to those, I have noticed, as others before me have noticed, a wasting of the tissues other than the muscles of limbs.

These concern, in the hands, loss of substance in the soft parts of the digits, the wasting of the skin, which brings about a satiny or glossy quality of the surface, and a dwindling of the nails, which we see carried to the full in extreme true gouty affection of the fingers, where the nails become small scaly appendages of the carrot-like digits. In some cases, I have also observed exaggeration of the so-called tendon-reflexes, and in some, fibrillar tremors. In fact, as they present themselves to me, these are cases of progressive dystrophy of joints marching with progressive atrophy of muscles, and with atrophy of the other tissues of limbs. My friend, Dr. Hadden, who has taken great interest in these cases, has recently presented a paper to the Clinical Society of London, taking up some of the points here mentioned. I may here relate two cases which bear upon this relation.

M. K., a married woman, aged 60, was recently under my care. There was no history of gout or rheumatism in her parents, but she had one sister, who was said to suffer from gout. She presented the lesions of rheumatic arthritis in the hands, knees, and ankles, but the hands were most affected. The muscles of both arms were distinctly wasted; the skin of the ends of the fingers was glossy, and the soft tissues around the two last phalanges were much wasted. The right hand was affected more than the left. The tendon reflexes were greatly exaggerated, both at wrist and elbow, particularly on the right side. The hands showed the adduction deformity of chronic rheumatic arthritis, rather than the claw of progressive muscular atrophy. The electrical reaction, of both kinds, was lessened; she had, therefore, slowly progressing in company, arthritis, wasting of muscles, wasting of tissues generally, and wasting of skin, without the reaction of degeneration. I could, in her case, detect no reflex cause. She was anæmic but not thin, and had worked hard. The case certainly pointed to a common central nervous origin of all the dystrophies.

A case now under care is more interesting. The patient, a man, following the occupation of salesman, and not the victim of overwork, has been ill for ten or twelve years. He suffered from rickets in childhood; there is no record of acute rheumatism in his own life, or of any joint-affection in his ancestry. When first ill, he had occasional attacks of weakness in his limbs, accompanied by swelling in the ankles, knees, wrists, and fingers, never in the shoulders or elbows. These attacks came and went, leaving him, at first, well in the intervals, but for some years he had not been possessed of proper muscular power. Two years ago he was violently shaken by a thunderstorm, since which the symptoms of which he now complains have appeared. He has now, typical rheumatoid arthritis of the hands and feet; the right shoulder is stiff and painful on movement, particularly in abduction; there is grating; and a rim can be felt around the articular end of the humerus. The elbow is not involved, but the wrist is greatly distorted, almost to dislocation. There is waisting of the interossei of the hand, of the thumb-muscles, of the muscles of the forearm, and in an excessive degree of the right deltoid; the right biceps being also, but not so profoundly, wasted. There is no paresis, only such loss of motor power as would

correspond to loss of muscular substance. Marked fibrillar twitchings can be seen in the arms, being more active in the right. The feet show chronic arthritis without any notable wasting of muscles. The knees are slightly affected, the hips free. There is no loss of sensation anywhere, and no impairment of the functions of bladder or of the rectum. The deep reflexes are rather diminished, the superficial not affected. The electrical reactions of the muscles chiefly affected are impaired. The right deltoid is much less sensitive to the galvanic current than it should be, and responds only to a Faradic stimulation stronger than that which should normally excite it. The biceps gives the same reactions in a lesser degree. The other muscles have normal reactions. In this case there is no history of gout, of lead-poisoning, or of causes likely to give rise to spinal trouble. These dystrophies of muscle and nerve are not accompanied by dystrophies of skin. The joint-affection was, to all appearance, preceded by a distinct accession of muscular debility.

Cholera Infantum and the Hydrencephaloid Condition.

The hydrencephaloid condition, or spurious hydrocephalus, is liable to develop as a sequel of badly-treated cholera infantum; and in order to call attention to this subject, Dr. John Strahan read a paper before the last meeting of the British Medical Association.

When spurious hydrocephalus is coming on, all fever which existed previously in cholera infantum disappears, and the temperature becomes subnormal. There are irritability and fretfulness, with hoarse cry.

Then comes on the somnolent stage. The surface is cool, the skin pale, the pulse quick and weak, the eyes half closed, sunken, and surrounded by wide dark circles; the fontanelle, if still unclosed, is concave, the head cool. The child ceases to take notice, the pupil is insensitive to light, the head is rolled frequently from side to side, the child gradually becomes more drowsy. If the case be neglected or improperly treated, coma gradually comes on, then convulsions and death.

Regarding the diagnosis of this state, all symptoms of inflammation or congestion are wanting, and the stupor or coma is not accompanied by squinting, inequality of the pupils, labored respiration, irregular pulse, or other symptom of inflammation, except the drowsiness. An important point is to carefully ascertain the history of the case, also whether any sufficient cause for nervous exhaustion and cerebral anæmia exists, or has lately existed. In a very doubtful case, the use of the surface-thermometer, to ascertain the temperature of the scalp, is desirable, as in this affection the temperature is rather below normal; but in any affection attended by hyperæmia, the reverse is the case.

The first and most important point is to stop the vomiting, as, while this goes on, the patient cannot be nourished, nor can the diarrhœa be arrested. He has found one-sixth of a minim of creasote and one-half minim of tincture of iodine, in a drachm of camphor-mixture, given every half-hour, or repeated immediately for a few times if rejected, by far the most effectual prescription for vomiting; often it acts likes a charm. At the same time, between the doses, he gives one-twelfth of a grain of calomel, or one-third of a grain of hydrargyrum cum cretâ, rubbed up with a few grains of sugar of milk or magnesia. Often this checks the diarrhœa in a few hours, when, of course, the interval between the doses is prolonged gradually. If the diarrhœa be very frequent, at the rate of forty or fifty discharges in a day, or if a few doses of the mercurial do not seem to produce some impression, he combines the hydrargyrum cum cretâ with ten grains of bismuth, and gives it every two hours. When the violence of the attack is over, one-sixth of a minim of creasote, with ten grains of bismuth, or with lime-water, or with chalk-mixture, is continued, at gradually lengthening intervals, as long as any diarrhœa remains. But, should the case remain unimproved for twelve hours, he gives an enema of a drop or two, according to age, of tincture of opium, in a little starch. This restrains diarrhœa powerfully. In severe cases, he always stops the milk entirely, and feeds on barley-water as thick as good milk, with fifteen to thirty drops of port wine frequently. This strong barley-water much resembles milk in its properties, *minus* the casein. Beef-tea is badly borne in such cases; besides, it is a mere stimulant, and not so effectual as wine. All infants' artificial foods, and other forms of starch, are simply hurtful, as they pass through the alimentary canal changed, indeed, but not in the slightest digested, just as the casein appears as curds in the dejections.

As to the treatment of the hydrencephaloid condition, should it unfortunately set in, the diarrhœa, if still present, must be stopped at once, if possible. But whether diarrhœa be present or not, the child should have a hot poultice, faced with mustard, applied to the nape of the neck, also some very hot application to the cardiac region, on account of the powerfully-stimulant effect of local heat on the heart. He then gives about ten minims of aromatic spirits of ammonia in camphor-mixture every two hours, and, at a different time, a drop or two, according to age, of Ashburton Thompson's tincture of phosphorus in a little mucilage. If the digestion will permit it, good milk for food, not less than a pint and a half, or more than two pints in twenty-four hours, with frequent doses of ten to twenty minims of brandy. Should the digestion not permit of milk, then the raw-meat plan finds its most useful application.

The nurse should be cautioned against raising the child into the upright position; the body-heat must be kept up by some means, or the child will die; plenty of hot flannels and a heated room usually are best, but the ventilation of the room should be very good. By such means, a wonderful improvement is often obvious in one or two days, and frequently recovery is complete at the end of three days. Should the hydrencephaloid condition come on without previous cholera or diarrhœa, as it sometimes does after weaning, from loss of blood, *e. g.*, by leeches, from improper use of cathartics, or, indeed, from exhaustion from any cause, even from improper treatment of the early stages of the complaint itself, the treatment is just the same; and whenever we see the

surface of the fontanelle concave and depressed, we should put thoughts of cerebral congestion and tubercular meningitis out of our heads, and diligently employ every means of tone-giving, stimulation, and support.

Causes of Death.

In the *Edinburgh Med. Jour.*, February, 1884, Dr. John Haddon says:

Having kept the counterfoil of the certificate of death, I am able to look over all the deaths with which I have met during eleven years of general practice in a suburb of a large town in England. The retrospect points out some facts which may be regarded as of general interest.

Altogether the deaths number 175, giving about 16 for each year. There were 94 males and 81 females. The following table of some of the common causes of death shows the number of deaths, and the proportion which the males bore to the females in each case:

Disease.	No. of Deaths.	Males.	Females.	Sex not noted.
Phthisis	17	3	13	1
Pneumonia . . .	17	9	8	0
Meningitis . . .	16	12	3	1
Bronchitis . . .	13	6	7	0
Cardiac	11	5	6	0
Scarlatina . . .	9	3	6	0
Typhoid	9	5	4	0
Measles	4	3	1	0
Smallpox	4	0	4	0
Erysipelas . . .	3	1	2	0
Diphtheria . . .	2	2	0	0

The following points seem worthy of note:

1. That diseases of the lungs cause 35 per cent. of the deaths, while all the infectious diseases put together cause only 27 per cent. of the deaths; and yet it is on the subject of the infectious diseases that the health officer and the public are most anxious. It may be that if diseases of the lungs were notified, and their etiology as carefully studied as that of infectious diseases has been, some startling but useful inferences might be arrived at as to the clothing and housing of the people.

2. That for every male that phthisis killed, it killed 4 females.

3. That pneumonia caused 17 deaths:

8 one year or under (catarrhal);
3 between 30 and 40;
3 " 40 and 60;
4 " 60 and 92.

From such figures we may infer that catarrhal pneumonia is very fatal to infants.

4. That bronchitis caused 13 deaths, of which 3 occurred below 6 months of age, and the rest between the ages of 54 and 81 years. The conclusion that bronchitis is seldom fatal except in advanced years, seems fully warranted.

5. That meningitis caused 16 deaths, of which no fewer than 12 were males. Unlike phthisis, this disease appears to kill 4 males to every female:

6 about or below 1 year;
4 between 2 and 3 years;
1 at 6, 7, 13, 49, and 58 years.

Thus it would appear that up to the age of 3 years, meningitis is a common cause of death.

6. That cardiac diseases caused 11 deaths, amongst which are included 2 cases of ulcerating endocarditis.

7. That although cases of pleurisy and acute rheumatism were commonly met with in practice, they do not occur among the causes of death, from which we may infer that these diseases are by no means frequently directly fatal.

In conclusion, I am aware that mistakes in diagnosis will occur, and that I have but few cases from which to generalize; nevertheless, knowing the great doubt as to diagnosis which shrouds the registrar-general's returns, I venture to submit this as my contribution to the literature of a subject which will be of importance so long as man is an inhabitant of this earth.

Treatment of Sick Headache.

Dr. Richard G. Jack reports this instructive case in the *Lancet*, August 23, 1884:

Mrs. N., aged 26, married, two children, had all her adult life suffered to some extent at the periods, and also was troubled with what is commonly called "sick-headache." She was treated by various doctors in the Western States of America, and at length she sought the advice of Dr. Thomas, of New York. He came to the conclusion that the only possible relief was to be obtained by removal of the ovaries; that she was then much too broken down for the operation: but after a trip to Europe had set up her health, he would, on her return, operate. I first saw the patient in June, 1883. She was then in the second day of the period, and under one of her headaches. These begin in one side of the head, and the pain gradually increases until the patient loses consciousness, the limbs become rigid, the hands clenched, the eyes half open and turned up, and ahivering fits come on every few minutes. At other times the attack takes the form of spasm of the glottis. Seeing her first in one of her severe attacks, I introduced my hypodermic needle, and injected one-sixth of a grain of morphine. I left the needle in, and in seven seconds relief was obtained; but as it was not complete, at the end of five minutes I gave the same quantity, and withdrew the needle. The pain subsided, and did not return during that period, but the patient suffered from severe sickness, which lasted thirty hours. In a few days I ordered iron and quinine, with shower-baths, good food, and early hours. When the next period was expected, I gave belladonna and bromide of potassium. As soon as the period came on, I kept the patient in bed, applied a blister of the size of half-a-crown over each ovary, and ordered a morphia pessary at night. The period passed over without a sign of pain or trouble. The tonic treatment was resumed, and the patient's health was steadily improved. The next period was anticipated a day or two with the belladonna and bromide, and when the flow began she was kept in bed the first day with half a mustard leaf over each ovary. No pain; period normal. On the next occasion, feeling the restraint irksome, and forgetting the date, the patient went to a theatre on the very

night of the return of the period, and at 1 a. m. I was sent for. I injected one-third of a grain of morphia; the relief was instantaneous, and by increasing the dose to half a grain the sickness diminished. I tried the addition of atropine, but without effect. By persistence in the treatment, essentially the hypodermic, the patient is freed from headache, and no longer looks sick in mind and sick in body, having regained color in her cheeks. I have repeatedly seen the same good effect in ordinary sick-headache, either from hypodermic injection of morphia or from a dose of chlorodyne.

Reviews and Book Notices.

BOOK NOTICES.

A Text-book of Pathological Anatomy and Pathogenesis. By Ernst Ziegler, Professor at Tübingen. Translated by D. MacAlister, M. D., Part II. New York: Wm. Wood & Co.

A Manual of the Throat and Nose. By Morell Mackenzie, M. D., New York: Wm. Wood & Co.

These two volumes are parts of "Wood's Standard Medical Authors;" the last named is Dr. Mackenzie's well-known work, which we have recently noticed, and which occupies a deservedly high rank among authorities on that branch.

Prof. Ziegler's treatise deserves particular commendation for the absence of superfluous matter in it, the clearness of its arrangement, and its conscientious accuracy of statement. It is illustrated with numerous woodcuts, so essential to a volume of this character. As it is by a practical teacher of the branch, its presentation of the subject is especially adapted for those who wish to master its intricacies for the first time.

Proceedings of the Philadelphia County Medical Society. Vol. VI. Philadelphia: 1884, pp. 416.

This volume, exhibiting the results of something less than a year's work, would be a credit to any society, and is one that Philadelphia physicians have a just right to be proud of. It is not only the amount but the quality of the work to which we refer. Questions both of practical and theoretical interest are discussed, not by a comparison of the opinions of others, but from the results of personal observation.

Of the many topics treated, we may mention the bacillus tuberculosis, the use of hamamelis, the medicinal uses of naphthol, the treatment of psoriasis, nervous prostration, hygiene of the kidney, paroxysmal fever, treatment of syphilis, contagiousness of phthisis—all topics, it will be observed, of immediate importance to the practitioner, and just such as he would like to hear the last word about.

The volume is published by the Society, and may be had by application to the secretary, Dr. M. S. French.

The absence of a table of contents, and a very insufficient index, are blemishes which we hope to see removed from the next volume.

Proceedings of the Nebraska State Medical Society. 16th Session. Pp. 357. Lincoln, 1884.

The larger part of this volume is taken up with the daily proceedings, and the reports of the committees on surgery and obstetrics. The surgical section is especially full, and contains descriptions of several new operations and instruments. The full text of the criticism of Prof. Esmarch on the treatment of President Garfield's wound will be read with interest. Spontaneous dislocation, intussusception, carcinoma, and wounds, are other topics on which there are well-prepared papers. In the obstetric section, puerperal fever and convulsions, placenta prævia and ovariotomy, have papers and illustrative cases. A table of contents would have improved the book.

The Theory and Practice of Medicine. By Frederick T. Roberts, M. D. Fifth edition. 8vo., pp. 1008. Philadelphia, P. Blakiston, Son & Co.

Dr. Roberts' treatise has secured a firm position as a valued addition to our medical literature. That it now appears in its fifth American edition is sufficient proof of that. Its merits are that without being inconveniently bulky, it contains all that is essential; that the author's style is plain and clear, without that affectation of profundity that mars some American books that we could name; and that his therapeutical advice is always safe, though at times it may be too nihilistic to suit all tastes.

The present edition has been carefully revised, and in part rewritten. The chapters on diseases of the nervous system have received especial attention, and the subjects of ophthalmology, electricity, and diseases of the skin, have been revised by specialists in those departments A number of illustrations add to the value and neat appearance of the volume.

The objection to many of the writers on practice is that they write from some particular point of view. They are rationalists, or physiological therapeutists, or therapeutical nihilists, or seekers after novelties. Of course, this lames their judgment and lessens the worth of their productions. None of these charges can be laid at the door of the present author, and hence we like his book.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium.	**6.00**
Physician's Daily Pocket Record,	**1.50**
Reporter and Pocket Record,	**6.25**
Reporter, Comp. and Pocket Record,	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A $10.00 BOOK FOR $2.00!

52 Steel-plate Portraits of Medical Men.

Having purchased the few remaining copies of ATKINSON'S PHYSICIANS AND SURGEONS OF THE UNITED STATES, containing 52 admirably executed steel portraits of eminent medical men, and the biographies of several hundred, I offer a copy to any subscriber to the REPORTER, who will send $2.00 and the name of a new subscriber to the journal who will agree to pay $5.00 within 30 days.

This handsome book of 788 pages is neatly bound in half morocco, and sold, when published, for *ten dollars*. But few copies remain, and they are entirely out of the market. As an illustrated album of the profession, it is an ornament to every library and office table.

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE CAUSES, PATHOLOGY, AND TREATMENT OF ALBUMINURIA.

As evidencing the narrow limits of our knowledge concerning albuminuria, the discussion which took place at the last meeting of the British Medical Association was striking; and as setting forth just about what we do know on the subject, it was satisfactory. Dr. George Johnson, who is an authority on the subject, tells us that it seems to him that the albuminuria which appears to have resulted from mental and emotional influence is a form of albuminuria from dyspepsia, and the immediate canse of the renal disorder is the excretion of some abnormal products of imperfect digestion. In many of these cases, too, it is obvious that more than one etiological agency has been operative. The man or the woman depressed by mental anxiety, with failing appetite and disturbed sleep, often seeks temporary relief from misery in an alcoholic stimulant; and so it is often found that the noxious influence of alcohol as a substitute for wholesome food has to be taken into account in explaining the albuminuria and the renal degeneration which had their starting-point in mental worry.

This gentleman does not believe that high arterial tension is a cause of albuminuria, and he reasons very logically as follows:

"As the Malpighian capillaries are the source of the albumen in the urine, and as the contraction of the arterioles which gives rise to the arterial tension tends to lessen the pressure on the capillaries in front, we should rather expect to find an inverse relation between the degree of arterial tension and the amount of albumen in the urine; and something like this is actually observed in the advanced stage of the small and granular kidney; where, with very high arterial tension, the amount of albumen is rarely copious, and sometimes scanty, and even for a time entirely absent."

In connection with the discussion on "Physiological Albuminuria," which has been recently occupying the time of the physicians of Great Britain, and more especially of Scotland, this au-

thor considers that the smallest trace of albumen in the urine is always pathological.

By far the most numerous class of cases of albuminuria in apparently healthy persons, is that of individuals who are known to have suffered at some former period from an acute renal disease, with or without dropsical complication. The acute symptoms having passed away, the patient believes and declares himself to be quite well. There is no irritation of the bladder, and no complaint of pain or uneasiness; the urine is normal in appearance, specific gravity, and quantity, but it contains more or less albumen. When cases of this kind are carefully watched, as they should be, it is found that, after a very variable period, the signs and symptoms of incurable degeneration of the kidney are developed.

The longest interval that he has known between an attack of scarlet fever with acute renal dropsy, followed by persistent albuminuria, and at length a fatal degeneration of the kidneys with uræmia, is thirty years. Yet, up to within a few months of his death, the subject of that disease was doing the work of an extensive and laborious general practice.

Until the practice of testing the urine in every trivial ailment for which a patient consults a medical adviser becomes general, many cases of albuminuria in persons apparently healthy will escape detection, until they have passed into the stage of hopeless and incurable degeneration of the kidneys.

Sir Andrew Clark and Dr. W. R. Thomas took part in the discussion of the subject, and it would seem to be the opinion of these three distinguished authorities that albuminuria (persistent) and the presence of tube-casts in the urine can be accepted as evidence of kidney disease. Of course, albumen can be found in the urine when there is no renal disease; for Sir Andrew Clark tells us that in a good many women, for a few days before and a few days after menstruation, the urine, free from blood discs, leucocytes or pus, contains, sometimes continuously, sometimes intermittently, small quantities of albumen. In women guilty of habits of secret personal impurity, a serous fluid is sometimes secreted into the vagina; and, afterwards, mixing with the urine, is found therein, responding in the usual manner to the tests for serum-albumen. In eczema of the bladder, in the early stages of villous tumor, and in the venous congestions of aged men, albumen transudes into the vesical cavity, mixes with the urine, and may readily be mistaken for albumen of renal origin. In forming an opinion, these possibilities must be taken into consideration, and it must also be remembered that renal and non-renal albuminuria may co-exist. Dr. Thomas believes that alcoholism has more to do with the production of Bright's disease than we give it credit for. He does not mean the taking of alcohol in large quantities, but that constant and regular taking of it, which is such a common custom. We so frequently meet with Bright's disease amongst very steady, hard-working men among all classes, that we are apt to lose sight of the fact. Because no excess has ever been noticed on the part of the patient, we close our eyes to the fact that many such steady-going men drink their two or three glasses of whiskey at night, their two glasses of sherry for luncheon, and two more, perhaps, for dinner. In addition to this, they sometimes take more during the course of the day, especially if they are business men. There are many men who can take their six glasses of something a day for years—yes, for a lifetime—without appearing to suffer in any way, thanks to the healthy organs which have been given to them, and which are day by day working hard to throw this off; but generally the day of reckoning comes sooner or later, often rather late in life. If we see such patients early for other ailments, we find that they complain of a desire to get up in the night to micturate, and alcohol may often be found in the urine. This desire he has always found a valuable premonitory symptom, present when hardly any others were; and whenever he has found it, he has generally examined the urine, and found frequently albumen also; but the appearance of the latter is generally intermittent, dependent, he believes, upon the taking in of a more than usual quantity of

alcohol the day before. These patients complain of frontal headache, confusion of intellect, and feeling of fullness in the head. The sight is impaired. They have a catarrhal condition of the pharynx, larynx, and nose, and are constantly hawking and perhaps coughing. They also have symptoms of dyspepsia, such as flatulence and sickness.

Upon the question of treatment they are agreed, and their recommendations may be summed up in the words of Dr. Johnson about as follows:

"One of the main principles in the treatment of albuminuria is to lessen, as far as possible, the work of the kidneys, and to obtain for them physiological rest. Amongst the most efficient means for obtaining this object, are rest in bed in all acute and severe cases, the promotion of the secretions of the skin and bowels, and, above all, a scanty diet, with entire abstinence from alcoholic stimulants. An exclusive milk-diet is often most successful in the treatment of recent acute cases; the plan being to give half a pint of milk to an adult about every two hours, and to continue this diet until the urine has entirely ceased to be albuminous. It will sometimes be found that, when the albumen has disappeared while milk alone is being taken, a small meal of solid food, fish, or poultry, or mutton, excites a reappearance of albumen. The patient and the friends often look upon milk-diet as allied to starvation, and frequent requests are made for some addition to the dietary. In reply to these complaints and petitions, I am in the habit of quoting the case of a gentleman, a patient of my own, who, in 1873, at the age of fifty-five, being seriously ill with disease of the kidney, the result of too generous living, was placed upon an exclusive milk-diet, which he continued uninterruptedly for a period of nearly five years, never taking even a biscuit or a piece of bread, except when he was traveling, and could not obtain milk. He lived in the country, and kept his own Alderney cows, which gave milk so rich in cream that he found it necessary to have the milk skimmed in order to obviate his tendency to excessive obesity. His usual allowance was a gallon of skim-milk daily. During the fifth year of an exclusive milk-diet he declared that he never felt better in his life; he was cheerful, slept well, and, at the age of sixty, was capable of taking a considerable amount of active exercise. After this, he gradually added to his dietary by taking soup or beef-tea, and the yolk of an egg for breakfast. In 1879, he took meat once a day. Since then, he has gradually returned to ordinary diet, and takes a glass or two of sherry a day. For six or seven years, he had abstained entirely from alcoholic liquors. I last heard from him in October, 1882, when he reported that, with the exception of some soreness of the tongue and lips, he was in good health. He had learned to test his urine, and found sometimes no albumen—never more than a trace.

"The chief interest of this case is the length of time during which a country gentleman, accustomed to a very generous mode of living, including a liberal allowance of wine, was contented and happy upon an exclusive milk-diet, his health meanwhile having very much improved."

THE INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE.

We have already adverted to the Collective Investigation of Disease, which has been in such successful operation in England for some time; and now we are pleased to note that Sir William Gull delivered a most valuable and pointed address before the International Medical Congress, at Copenhagen, in August, in which he strongly advocated the advantages to be derived from a system of international collective investigation. He very truly said that while it will always be the privilege of the highest intelligences to clear the boundaries of knowledge, and to throw the rays of their genius into the surrounding darkness, yet all must be agreed on the great and almost supreme value of the intellectual co-operation of less gifted minds in the simple observation of facts, and especially when the needed facts are scattered over a wide field.

The observations of one man, who has a keen perception, are of course of great value; but how much more valuable would be the observations of thousands, from whose combined experiences certain absolute and definite facts could be deduced—for happily the phenomena which demand our investigation, though complicated and transient, are, it need not be said, the result of unchangeable laws. The capriciousness of Nature, as we speak of it, is but the weakness of our own sense and understanding, and its so-called mystery and obscurity, but the darkness in ourselves.

"We may therefore have this encouragement,"

says Sir William Gull, "that, when any of our work is done, however small and trifling it may seem, it is done and settled for all time, or at least so long as the laws of organization remain what they are; that the clearing of a fact in respect of disease will remain an imperishable inheritance of knowledge to those who follow us, so long as there is disease in the world. We may support our labors, therefore, with a feeling of surety that the problem before us is a settled problem, however difficult its solution. Nature will not delude us, however much we may delude ourselves."

It is only necessary to add that Sir William Gull's suggestion was favorably received by the Congress, and that representatives from each country were appointed, whose duty it shall be to forward this project. We most heartily commend it to our readers, and urge upon them to respond liberally and earnestly to any requests that may be made of them in connection therewith.

Notes and Comments.

Massage.

Before the late International Medical Congress, Dr. Zubelndowsky (Berlin) read a paper on this subject. He said that, in stiffness of joints and ankylosis, the restoration of normal function was not always to be obtained. The treatment by massage was generally longer in private than in hospital practice; it was of longer duration in diseases attendant on occupations. It was not advisable to combine massage and bath-treatment. The prescription of ordinary friction (in the baths) along with massage was a source of many inconveniences to the patients. The simultaneous use of massage and electricity afforded no advantage, and the same was the case with cold douches. Massage and lukewarm baths went well together. Orthopædic apparatus had come too much into use, and could often be advantageously and with comfort replaced by massage. In hysterical patients, massage was a hypnotic and cumulative agent, even when applied to limited portions of the body. In the sick as well as in the healthy, massage often at first produced increased tenderness and suggillations, which disappeared with continuance of the treatment. Diseases of the knee had a greater influence than diseases of other joints on the general condition, both physical and mental; and, on the other hand, mental excitement might give rise to neuroses of the knee-joints. Sympathetic neuroses occurred most frequently in the knee. Exhaustive neuroses arising from mental disturbance, like those connected with occupations, offered a profitable field for massage, as did also inflammatory conditions of joints consequent on disuse and rest. Massage should form an integral part of the after-treatment of traumatic injuries of greater or of less extent. In recent fractures, massage was injurious; in pseudo-arthritis it was very useful. The so-called nerve-pressure of many of the Swedish lay practitioners was to be avoided.

Alcoholism in Childhood and Youth.

Dr. Thomas More Madden somewhat surprised the members of the British Medical Association at their last meeting, by telling them how comparatively common among children of very tender years was the habit of consuming alcohol, and how many cases of juvenile, almost infantile, diseases, the results of alcoholism, he has been called upon to treat. By way of illustration, he related five cases. The first was a well-marked case of delirium tremens in a boy aged eight; the second a boy of the same age, suffering from chronic alcoholism, and so on. Of course, as we might infer, these cases are found amongst the lowest classes of society, where the parents are in the habit of sending their small children to the neighboring public houses for liquor; oftentimes on the way home these little ones will take a "taste" from the pitcher, which sows the seed that germinates into an irresistible desire for alcohol; while in other cases, the parents (through ignorance, no doubt,) will reward the little ones for running the errand with a sip of porter or spirits. Again, it would seem, according to Dr. Madden, that these drunken women transmit a taste for liquor to their offspring. The habit of drinking among women (which is much more prevalent among the higher classes in England than in this country) is often produced by physicians recommending liquor for women suffering from some uterine disease. Therefore, Dr. Madden issues the advice, and those who heard agreed with him, that when a physician desires to give a patient the benefits of the stimulating influence of alcohol, he should prescribe it as a drug in definite doses, and not as liquor to be used at the discretion of the patient. Similar views were enunciated by the Philadelphia County Medical Society last winter.

The Communicability of Phthisis.

Notwithstanding the immense amount that has been written and published concerning the communicability of phthisis since Dr. Koch first announced his discovery of the bacillus, we seem to be no nearer a unanimity of opinion on the subject than we were a year ago. The whole question seems to be about as follows: That for the disease to develop there must exist some constitutional peculiarities, the intricate nature of which we have not yet grasped. Dr. Alfred G. Barrs, who contributes an article to the *Lancet*, August 23, 1884, seems to hit the nail on the head in the following conclusions:

1. The tubercle bacillus is constantly found in all lesions of a tubercular nature, and in all cases of pulmonary phthisis in the human subject.

2. So far as the communicability of tuberculosis in animals is concerned, this is clearly proved by inoculation experiments. Whether it is so without antecedent transmission there is very little evidence to show.

3. The great prevalence of phthisis amongst those of certain occupations, and the comparative rarity with which those presenting caseous changes in the lungs die by means of a general infection, tend to show that certain predisposing causes are necessary for the production of phthisis—some more definite condition than a mere obliquity of construction, such as we mean by constitutional tendency. The bacillus is not in this case the real and primary cause of the disease, but by its constant presence may determine a wide distribution of the lesion and a fatal result.

4. Although the discovery and isolation of Koch's bacillus, and the inoculation experiments upon animals, make the direct infection of individuals with tuberculous matter possible under certain conditions, these conditions are not established by our present mode of life.

5. The clinical evidence of direct infection from man to man is at present of a quite untrustworthy nature. I need scarcely add that the want of proof of direct contagion in no way militates against the view that pulmonary phthisis is an infectious disorder—that is, due to the introduction of an infective particle from without.

Torsion of Large Arteries.

Before the late International Medical Congress, Dr. Oscar Wanscher (Copenhagen) read a communication on the torsion of large arteries near their bifurcation. He had, he said, had no cases of his own, but he had experimented on the common iliac artery of the dog in six cases, and on the common carotid of the horse in nine. If peripheral torsion were made (as of the common iliac near its origin from the aorta), the retraction of the inner coat, even though limited, was sufficient to prevent hemorrhage. In torsion of an artery nearer the centre of enucleation, as of the common carotid near its bifurcation, the chances were not so good; but, if a short time were allowed to elapse between the interception of the flow of blood and the act of torsion, so as to permit the establisment of the collateral circulation, the retracted portion would be carried some distance by the blood-current. Retraction should be extensive in an artery of the size of the common carotid of the horse. Torsion alone could hardly be considered sufficient in the vicinity of large collateral branches; but, in such cases, retraction deserved to be regarded as an excellent aid. Retraction of the membranes might take place without compromising the inner vitality of the artery or causing extensive coagulation, provided that proper instruments were used, especially one to compress the artery, and push back the inner membranes.

Incision of the Initial Sclerosis in Syphilis.

Apropos of this vexed question, we note that before the late International Medical Congress, Prof. Pick (Prague), in a paper on this subject, said he confined his remarks to hard chancres, and distinguished carefully between those cases in which the glands were indurated and those in which they were not. Where the glands were affected, these also must be excised; but in such cases, almost without exception, whether excision was practiced or not, general symptoms made their appearance. The conditions under which the operation might be performed were only partially known. Simple excision of the sclerosis, where the glands were affected, would never give success; and no excision availed when the deep glands were swollen. The effect on the therapeutics of the condition was, he thought, very slight—most commonly only a delay in the appearance of the general symptoms. The operation had, however, served to show that the indurated sclerosis was not the expression of general syphilis. The lymphatics had recently been found to be much enlarged in these cases, and he believed that the syphilitic poison passed into the organism through these, and not, as Auspitz believed, entirely through the blood.

Dr. Unna (Hamburg) believed that syphilis spread, not by any one path, but by both the

blood-vessels and the lymph-vessels, and by simple contiguity of tissue.

A Peculiar Case of Chronic Nephritis.

The Paris correspondent of the *Brit. Med. Jour.*, August 30, 1884, says that M. Hanot has had recently in his wards at the Tenon Hospital a female patient, suffering from chronic nephritis, who was suddenly attacked by gangrene of the left foot and leg. Her affection was easily diagnosed. All the essential symptoms were manifested—*bruit de galop*, albuminuria, uræmia, etc. She left the hospital in June, but was forced to return in July; and, on the 17th, she felt a violent pain in the gastrocnemius muscle of the left leg, also a sensation of cold along the entire limb and foot. The vessels in the popliteal space were hard and painful. The foot was cold and colorless, afterwards mottled; gangrene immediately appeared, and reached as far as the knee. In about eight or ten days the limb became almost severed from the trunk; there was neither suppuration nor fever. The general condition of the patient was good, and her appetite remained excellent. M. Hanot suggests that arterial lesion, frequent in interstitial nephritis, may be the cause of this gangrene; but hitherto lesion of so important an artery has never been observed.

Treatment of Cystine in the Urine.

Dr. Lionel S. Beale tells us, in the *Lancet*, August 30, 1884, that cystine is one of the most persistent of urinary deposits. After it has once appeared, it may be produced, and in considerable quantity, over a period of twenty years or more, or its production may only cease with life. It is among the least common of urinary deposits, and usually its presence is not associated with any symptoms more serious or definite than malaise, a feeling of weakness, fatigue, or exhaustion, with depressed or very low spirits. The cystine crystals form a visible whitish deposit, which varies much in quantity from day to day; and sometimes forms a sediment. Dr. Beale claims that large doses of carbonate of ammonia will remedy this condition. He had one patient who took as much as fifty-five grains daily for a period of twelve months, with most satisfactory results. The second year he took thirty-five, and the third year about twenty grains per diem.

Neuralgia Treated by Cold.

The Paris correspondent of the *British Medical Journal* says that M. Debove, physician at the Hospital des Tournelles, treats his patients suffering from sciatica by refrigeration. His method hitherto has been attended in some instances by immediate recovery, and in others rapid, though not instantaneously. Chloride of methyl, enclosed in a siphon, produces a temperature of 10° Fahr., sometimes of 59° Fahr. The former is the degree necessary. Cold is applied along the nerve affected, which is not distressing to the patients; one of them declared that ten applications of cold were preferable to one of the actual cautery. When the neuralgia presents limited areas of pain, the jet is directed on them. The siphon with the tube fixed to it amounts to six or seven dollars. The chloride of methyl costs $1.25. M. Debove used Richardson's apparatus, but failed to obtain any results with it.

A Bottle in the Rectum.

A singular case is reported by Dr. Aug. Dixey in the *Lancet*, August 30, 1884. A man much distressed and evidently in great pain came to him saying he had a "soda-water bottle in his fundament." Upon at once letting down his trousers, which were covered with blood, he noticed blood trickling from the rectum. On introducing a forefinger into the bowel, he could just detect the edge of the mouth of a bottle, and, by inserting the middle finger as well, was able, after some difficulty and employing all the traction his limited hold permitted, to extract, not an ordinary soda-water bottle, but one which is used to contain ginger ale, the length of which was seven inches and a quarter, and the circumference seven inches. His story was that as his bowels had not been opened for more than a week, and as aperients had not acted, some one advised him to open them by means of a bottle, and that in attempting this it had slipped from his grasp, and all his efforts to get it again were unavailing.

Treatment of Cholera.

Dr. Henry Meymott puts in a plea (*Brit. Med. Jour.*, Aug. 30, 1884,) for "*crude* opium in the treatment of cholera. Let the external applications consist of the continuous supply of friction with hot flannels, wet or dry, to all the available parts afflicted with cramps till relieved, and sinapisms applied to the epigastrium. Then give half a grain of opium in a small hard pill, every hour till the pain subsides, washed down with a teaspoonful of cold water, previously boiled. Abstain from all nostrums and stimulating medicaments until the irritability of the stomach is overcome, and in the meantime give nothing but cold

water to assuage the thirst, then substitute hot drinks composed of smooth, fresh, water-gruel, flavored with salt. When the violence of the symptoms has fairly subsided, adapt the treatment to the fresh symptoms as they arise, always bearing in mind the "vis medicatrix naturæ."

Union of Wounds and Fractures in Old Persons.

It is so unusual for fractures to unite in aged persons, that all such cases are worthy of record. Dr. Edgar Schmidt reports a case in the *British Medical Journal*, Aug. 23, 1884:

The patient, a healthy German lady, aged 78 or 80 years, was in the act of plucking a bunch of grapes, when her foot slipped, and she fell from the first round of a ladder on which she was standing. The fall resulted in fracture of the neck of the left femur. Her limb was encased in a long splint with weights, and, notwithstanding her restlessness and obstinate spirit, she was able to walk with canes in six or seven weeks. No unfavorable symptom arose with the exception of two bed-sores, which, however, yielded kindly to the application of balsam of Peru.

The lady enjoyed moderate good health until one year after her fracture, when she died as a result of gangrene of her right foot.

The Treatment of Slight Burns.

The Carron-oil treatment of burns is so greasy, and therefore so disagreeable, that it is with pleasure that we note from *Memorabilien*, May 14, 1884, that Dr. Cramer treats slight degrees of burns by means of compression. He applies a layer of wadding and over this an elastic bandage, so as to make firm and even pressure over the whole of the injured surface. By this means the subcutaneous capillaries are emptied in a measure of their blood, and inflammation and exudation of serum are prevented. The compression is to be maintained from three to fifteen hours, according to the intensity of the burn, and then a less degree of pressure kept up until new epidermis has formed.

The Use of Crushed Ice and Lard in the Treatment of Burns and Scalds.

In the *Æsclepiad* for April, 1884, page 164, the treatment of burns and scalds by crushed ice and lard is warmly advocated by Dr. Benjamin W. Richardson. To put the method into practice, ice is well crushed, or scraped as dry as possible, then fresh lard is admixed until a broken paste is formed. The mass is then put into a thin cambric bag, laid upon the burn or scald, and replaced as required. The pain is rapidly eased, and its return is the call for the repetition of the remedy. This mode of treatment is as scientific as it is simple. It saves at once the fever incident to pain, and it leaves very little contraction of surface.

In-growing Nail.

In a note to the *Union Médicale*, June 22, M. Monod states that during the last twenty years he has treated in-growing nail by a very simple and effectual method, which does not involve the removal of the nail. He makes a free application of nitrate of silver at the commencement of the affection, without isolating the nail. If the cauterization is carried deeply into the diseased furrow, the patient has usually, even by the next day, derived considerable relief, and is able, even thus early, to walk in moderation with an easy shoe. Extirpation of the nail should be reserved for quite exceptional cases.

Correspondence.

Is it Always Necessary to Tie the Cord?

Eds. Med. and Surg. Reporter:

I ask this question, not because I feel confident of my ability to answer it in a way to settle it beyond hope of dispute, but because the question has been raised in my own mind by observation of the process of parturition in some brutes, and in a couple of cases in the "genus homo."

I know that most authorities unite in advising the ligation of the funis; some advising that the cord be twice ligated, and cut between the ligatures; some that it be "surrounded by one ligature," and cut on the maternal or placental side of ligature, leaving the placental end to *bleed*, with the end in view of lessening the size of the placenta, and consequently its more easy delivery; while other writers leave it to the discretion of the accoucheur whether he shall tie once or twice, but all seem to unite in advising the tying of the cord.

Now, in the light of the following facts, I feel justified in asking the question, May we not, in *many* cases, leave the cord without a ligature, and so avoid the risk of a troublesome sore, if not of septicæmia, from the cutting of the fingers with a cord stained and rendered slippery by the blood of a puerperal patient?

I do not open this question without facts to justify my action, but think that the following are enough to raise the question, though they may not prove the absolute correctness of its answer.

I have seen cats, when their kittens are born and the placenta delivered, turn and eat the afterbirth and bite off the cord.

In the case of pigs, I have seen young very soon after birth (in a few minutes) start in search of the mammæ of the sow, and break the cord in

their struggles for freedom of motion; and I believe it is very rare for a kitten or pig to die, or even suffer from hemorrhage of the cord.

Of other animals, except the human, I cannot speak; but I know that in the undomesticated state the funis cannot be ligated, and in the domestic animals I believe it is very rare for them to receive that attention.

Next. On page 390, vol. xlvii. of MEDICAL AND SURGICAL REPORTER, is a short editorial abstract from the *British Medical Journal*, entitled "Midwifery in the Sandwich Islands." In this abstract I find the following: "The umbilical cord is then cut, and always left very long," no mention being made of ligation.

Again, in the same journal (MED. AND SURG. REP.), page 564, vol. l., is an abstract from the *Edinburgh Medical Review*, bearing the title, "Parturition in Central Africa," by Mr. R. W. Felkin. In it I find this: "In the Wadi district the cord is cut at about four (4) inches from the chid's body with a stone knife as a rule, but sometimes it is bitten. Should it bleed, the woman in charge takes the cord in her mouth and squeezes it between her teeth till all hemorrhage ceases; *but it is never tied.*"

Now, I will relate two cases of my own:

Case 1. On April 4, 1884, at 1 p. m., R. W., a colored man living about five miles below here on the Sans Souci plantation, called at the office, saying that his daughter had given birth to a child and needed attention. I rode down with him, and found the mother comfortable and in bed, while from a bundle of rags on the cabin floor came a sound of lusty crying. I opened the bundle and found a negro child (boy), with the cord and placenta attached. *The cord was pulseless and bloodless,* and the child in as good condition as any I have ever had the fortune to see.

Case 2. Was called July 3d, 2 a. m., to attend Mrs. G. (white, multipara), in labor. I arrived at the house of the patient at 3 o'clock, and found the child with placenta attached, cord bloodless and wound once around the neck, lying between the thighs of the mother, where she said it had been since 2 o'clock, when it was born. The child was all right, and was crying as loudly as newborn children are wont to do.

In both of these cases I am satisfied that the children would have done well enough if the cords had been cut and left without ligation; and had they been *hospital* cases, and in my care, I would have left them for awhile, at least; but as I knew of the keenness with which country people watch a young physician, and the avidity with which they seize upon and circulate any departure from the usual course, I tied the cord in both cases.

Now, from these facts we see, first, that the brutes do not suffer because of the cord being left without ligature; second, that some races of people *habitually* leave the cord untied without ill effects; and finally that in two cases at home the cord was not tied for an hour in one case, and in the other at least one and one-half hours, and as all hemorrhage had ceased and the children were in good condition, it was absolutely unnecessary to tie the cords, although I did tie them to satisfy the notions of other people.

Now, I believe we may *almost invariably* leave the cord unligated. Do not think I would have you return to the primitive mode of biting the cord. either for the purpose of separating the placenta, or arresting the hemorrhage; but might we not advise a simple instrument, which would both *cut* the cord and compress it? All that would be necessary would be a pair of short-bladed shears made somewhat heavy, and having on the side of the blades a pair of bosses, whose corrugated or checked surfaces should come close enough together to compress, and if necessary to lacerate the end of the cord, and so arrest all hemorrhage very easily.

And now if this needs any apology, it is this: I *have* known some very sore hands, and one serious, though not fatal, case of septicæmia resulting from cuts with ligatures rendered slippery with blood of puerperal patients, and think that this may suggest a way in which we may avoid the risk in many, if not all cases.

Osceola, Ark.

A Peculiar Malformation.

EDS. MED. AND SURG. REPORTER:—

Mrs. E. F., æt. 25, strong and robust, of healthy parentage, the wife of a farmer also in good health, was confined on March 31, 1884, with her second child. The previous child had been well-developed and healthy, but died in infancy of an acute bowel trouble. Both labors were remarkably quick and easy, with no complications. At the time above cited, although I arrived at the house within an hour after the pains commenced, labor, even through the third stage, was completed.

Upon examining the child, the following singular and perhaps unique condition was discovered: In the first place, the child was a complete hermaphrodite, and that to a singular extent and in a peculiar degree. At that part where the sexual organs should have been, there was an utter absence of everything, except smooth skin covering the part; and where the anus should have been, there was a like smooth surface; while at the perineum, in the median line, was an anus-like opening, controlled by a sphincter, through which the acts of defecation and urination were and still are alike performed. Perfect control is exercised over both bowel and bladder. The evacuation of each is effected at certain intervals, and usually simultaneously, and with neither does there seem to be anything like incontinence, or want of perfect control.

The other feature, and the one that first attracted our attention, was the presence of a peculiar, semi-spheroidal, very vascular growth, plastered upon the surface of the abdomen, in the umbilical region. It measured 3x2x1½ inches, and bled at the slightest touch. From the centre of this growth proceeded the umbilical cord, which was of usual length and appearance, and was attached to a perfectly normal placenta. This growth, as was remarked by other physicians who subsequently saw it with me, had the exact appearance and feel of true placental tissue. The condition of things seems to have been: an umbilical cord with a placental development at each end, the one normally attached to the uterus, the other abnormally attached to the child.

The growth was not pedunculated, but was attached by a broad, firm base, 3x2 inches. The cord separated on the sixth day, with but little hemorrhage.

A discussion of the *causes* of this malformation would be interesting, and no doubt embryology would be equal to the emergency; but remembering to have heard an eminent professor remark that the most absurd thing he knew of was the wild speculations of a country physician, I gladly leave theoretical ramblings to a nimbler wit and a readier pen.

At this date the growth has decreased somewhat in size, is of very spongy texture, and bleeds readily upon pressure or irritation. Over its surface are several small islets of apparently true skin forming, leading to the hope that nature will thus protect that which surgery would as yet deem hazardous to remove.

Çedarville, N. J.

Treatment of Acute and Chronic Urticaria with Bromide of Ammonium.

Eds. Med. and Surg. Reporter :—

Within the last ten days I have treated three cases, two acute and one chronic, of urticaria with bromide of ammonium. The first case was that of a grocer, whose attack came on very suddenly about four o'clock in the evening. I saw him two hours afterwards, and he told me that he was taken a year ago exactly in the same way, with violent hives, and that in two days the attack was followed by facial erysipelas. His face and hands were red and swollen, and covered with hives, and he was rubbing and scratching in the most active manner. I prescribed the following:

℞. Bromide of ammonium, ℥ij.
Aqua destil., ℥vj. M.
Sig.—Shake well, and take a tablespoonful every two hours.

I directed him to take in addition ten grains of blue mass at bedtime and a dose of epsom salts in the morning. His urticaria disappeared during the night, and he had no return of it.

The second case was that of a clerk. He had been eating fish for a day or two, when suddenly violent urticaria made its appearance. I prescribed for him:

℞. Bromide of ammonium, ℥ij.
Aqua camphor., ℥vj. M.
Shake the vial well, and take a tablespoonful every two hours,

After the second dose his hives began to get better, and the next day they disappeared, without a return of them.

The third case was that of a young lady. She informed me that she had had the hives for three months. That they did not trouble her during the day, but just as soon as she got in bed at night they would come on and torment her dreadfully for two or three hours. I found nothing wrong with her but the hives, and I prescribed:

℞. Bromide of ammonium, ℥j.
Aqua destil., ℥vj. M.
Shake the vial well, and take a tablespoonful every three hours.

In four days she returned to thank and inform me that the mixture had cured her hives.

Washington City, D. C.

Alopecia.

Eds. Med. and Surg. Reporter:—

If Dr. George A. Stewart, of Scranton City, Iowa, (see Medical and Surgical Reporter, August 30, 1884, p. 250,) will turn to page 32, vol. 32, Medical and Surgical Reporter (1875) he will then find a case similar to his by Dr. Rose, from *Brit. Med. Jour.*, except that Dr. R.'s case experienced "a sudden and severe nervous shock" prior to his hair falling. He succeeded in curing by painting his scalp once a fortnight with blistering fluid and using the following lotion:

Carbonate of ammonia,	One drachm.
Tincture of capsicum,	One drachm.
Rectified spirit,	One ounce.
Glycerine,	One ounce.
Rose water,	Eight ounces.

To be applied freely over the body night and morning.

I think the doctor misnamed the disease (begging his pardon). Alopecia areata is defined to be, "a contagious disease produced by a vegetable parasite which, attacking the hair, leads to the formation of circumscribed, pale, smooth, bald patches;" hence the synonyms—"area," "alopecia circumscripta," etc. See Reynolds' System of Medicine," vol. iii., p. 942.

Dr. Rose's case, before alluded to, is very interesting, and will well repay a perusal. The patient's hair was restored on all parts of his body; but was perfectly *white*, having been brown before.

Platte City, Mo., September 2, 1884.

News and Miscellany.

Micro-Organisms.

From advance sheets of the Introductory Lecture at the opening of the fall course of the Medico-Chirurgical College, of Philadelphia, by Prof. Hugo Engel, we glean the following interesting points about micro-organisms. The address, in full, will be published in our columns. For a long time investigators were undecided whether micro-organisms, as they are comprehensively termed, belonged to the animal or the vegetable kingdom. It has now been decided that they belong to the latter. The terms *micro-organisms*, *microbes*, and *microzymes*, all mean the same thing. Micro-organisms are divided into two primary divisions: 1, Hyphomyceti, and 2, Schizomyceti. The first class are the pathogenic factors of external diseases, as favus, aphthæ and thrush; while the second cause the internal diseases. The schizomyceti are subdivided into the following classes:

1. Cocci or micrococci, which are small round bodies, and embrace the cocci of pneumonia, pigment cocci, and some ferment cocci.

2. Bacilli, which have a rod-like shape, whether long or short, such as the bacilli of typhoid fever and tuberculosis.

3. Bacteria *proper* (the whole class are often called bacteria), such as bacterium termo, the common grade ferment.

4. Vibriones or Vibrios, those which have a wavy form, as *probably* the comma bacillus of cholera.

5. Spirilli, in the form of stiff screws, such as many of the micro-organisms causing decomposition.

6. Spirochæti, in the shape of flexible screws and other fantastic forms, such as the micro-organism of relapsing fever.

It has been calculated by Ferdinand Cohn, that if the bacterium termo were unimpeded in its propagation, and if one were to multiply into two in the first hour and these into four in the second hour, and these into eight in the third hour, and so on, the result would be 16,000,500 in the first day, and 281,000,000,000 on the second day, and that in five days' time the progeny of this little microscopical body would fill the oceans of the world, so wonderfully numerous and fertile are they. One micrococcus, $\frac{1}{500}$ of a millimetre long and $\frac{1}{1000}$ of a millimetre thick, and of which 1,600,000,000 are required to weigh one grain, would in three days produce 50,000,000 pounds of offspring.

Teberine is a disease of the silk-worm that threatened to destroy the silk industry of France. Pasteur found a bacterium in ova that were apparently healthy; all such ova were destroyed, and the threatened danger was averted.
